ROGERS PASS ENVIRONMENTAL
ASSESSMENT PANEL

In the matter of Public Meetings of the
Environmental Assessment Panel on CP
Rail's proposed new track development
in Rogers Pass.

PANEL MEMBERS:

P.J. Paradine -- Chairman

Dr. W. Ross

Mr. G. Tench

Held in the Sandman Inn, Petroleum Room,
Calgary, Alberta, on Saturday, the 11th
day of June, 1983, at the hour of 2:00
p.m., Local Time.

1 THE CHAIRMAN: (Mr. Phil Paradine):

2 Good morning Ladies and Gentlemen.

3 This morning's session is on revegetation
4 reclamation and tunnel ventilation issues.
5 Visual impact assessment is also going to be
6 covered under revegetation reclamation.

7 We are going to start this
8 morning with a presentation by Mr. Fox's
9 consultants on revegetation reclamation followed
10 by the Panel's technical expert and then Parks
11 Canada; continue our discussion afterwards. After
12 those people have made their presentation and
13 when we are finished with that issue, we will
14 then switch over to the tunnel ventilation
15 acoustical issue, and we have speakers from
16 C. P. Rail, a consultant, and we also have a
17 Panel technical expert on that particular issue
18 as well.

19 Before we start I would like to
20 make one request to C. P. on the record -- not to
21 C. P. but to Parks Canada on the record, and that
22 is whether they could inform us whether they ever
23 had a camp site, workers camp site of the size
24 that is being proposed for this particular project
25 or what is the largest work camp that they have
26 had within their parks, within the system. I
27 realize that may take a bit of searching for, but
28 perhaps somebody could send us a letter or perhaps
29 you can delegate it upwards to Ottawa to find out
30

(MacGregor)

1 the answer to that particular one.

2 Therefore, we will move now
3 right away to I believe Mr. McGregor and then
4 Mr. Polster.

5 MR. JAMES McGregor, (MacLaren
6 Plansearch): Good morning Mr. Chairman, Members
7 of the Panel, Ladies and Gentlemen. I will just
8 preface my remarks by stating that the first ten
9 minutes of the presentation will deal with the
10 methodology that we used, and that will be
11 followed by about a 20-minute discussion on the
12 actual visual results, and that will be followed
13 by a presentation by Bruce Haggerstone on the
14 vent shaft.

15 In the introduction to our report
16 we noted that following a request from Parks
17 Canada and the Environmental Assessment Review
18 Panel, C. P. Rail retained the services of
19 MacLaren Plansearch to prepare a visual impact
20 assessment for the twinning of the C. P. Rail
21 through the Beaver Valley. The results of this
22 inquiry has been the preparation of one of the
23 most comprehensive visual impact assessments ever
24 taken in Canada.

25 The conclusions of that effort
26 are presented to you on the exhibit panels and in
27 this comprehensive Green document and during this
28 visual presentation. Should you have any questions
29

30

PM-A-3

(MacGregor)

1 about the content of these graphic exhibits,
2 please do not hesitate to contact my colleagues,
3 Bruce Haggerstone, John Foster or myself.
4

5 In our studies the visual implication
6 of the second track are considered from the
7 point of view of the travellers along the Trans
8 Canada highway where their scenic views would
9 be affected by the cuts and fills resulting from
10 track construction.

11 The study responded to the key
12 issues discussed in the FEARO Report Number 20:

13 "The most serious concern raised
14 related to the potential for terrain
15 impact along the surface route, and
16 the difficulty in achieving satisfactory
17 reclamation".

18 In addressing this issue the
19 visual impact assessment study developed a
20 comprehensive understanding of the existing visual
21 resources, assessed the landscape's capability
22 of absorbing the second track, provided design
23 guidelines necessary to minimize cuts and fills
24 and outlined mitigative measures and the monitoring
25 program necessary to adapt the new track to the
26 existing landscape conditions. We also considered
27 the visual impact of the ventilation shaft. As
28 I mentioned, Mr. Haggerstone will discuss that
29 later.
30

1 (MacGregor)

2 The basic purpose then of the
3 study is two-fold:

4 First, to protect as much as is
5 reasonably possible the integrity of existing
6 Park landscape, while at the same time permitting
7 the Beaver Valley to fulfill its role as a
8 transportation corridor of national importance.

9 The valley was studied in terms
10 of the perceptions of both the eastbound and the
11 westbound travellers. For the most part they
12 are across the valley from the proposed track
13 where they experience two distinct viewing
14 situations. First is from the top of Heather
15 Hill where views are directed south over the
16 length of the valley floor and the second set of
17 viewing situations are from the valley floor
18 itself.

19 It is important to note that
20 historically the Canadian Pacific Railroad has
21 been part of the visual and cultural heritage
22 of Glacier National Park for the past century.
23 In 1882, Major Rogers, an employee of C. P. Rail,
24 discovered Rogers Pass. Three years later the
25 railway over Rogers Pass was opened thus completing
26 an east-west link that encouraged British Columbia
27 to eventually join Confederation. Much of that
28 line is still in use today and exists as a faint
29 line along the west slope of the Hermit Range.
30

1 (MacGregor)

2 The Rogers Pass area was not only
3 developed as a transportation corridor but also
4 as a tourism destination region. In 1895 the
5 Canadian Pacific Railway built the Glacier House
6 Hotel, attracting climbers and hikers from around
7 the world.

8 We believe it is fair to say then
9 that there is a strong historic precedent for
10 C. P. Rail's involvement in the Rogers Pass area.
11 In fact, it may be assumed that the very existence
12 of Glacier National Park is, in part, linked to
13 the activities of C. P. Rail. The construction
14 of a second main line therefore represents the
15 continuation of a transportation heritage that
16 has characterized this region for the last century.

17 Before explaining our approach and
18 its results, let me first outline just the primary
19 objectives of the study. They were to firstly
20 work directly with the design staff of C. P. Rail
21 to minimize the adverse visual impacts of the
22 construction and operation of its second line, and
23 to provide ~~FEARO~~ and Parks Canada with the necessary
24 information to assess the visual impacts of the
25 proposed mitigative measures.

26 The approach was based on a
27 comprehensive inventory and analysis of the visual
28 features in the landscape; appreciation of the
29 visitor's experience as they travelled along the
30 Trans Canada highway; an understanding of the

1 (MacGregor)

2 inherent capability of the landscape to visually
3 absorb the facility; an ability to work
4 interactively with advance computer-aided designing
5 technology. The exhaustive inventory analysis
6 of all natural and man-made features was the basis
7 of the assessment process. Combined with an
8 all inclusive tabulation of various experiences
9 and perceptions of the visitor, it enabled the
10 consultants to have a sensitive understanding
11 of the potential effects of the proposed railway.

12 This appreciation was first applied
13 to identify specific key observation points.
14 Evaluation of these "KOPS", as we call them, indicate
15 the overall capability of the landscape in the
16 Beaver Valley view shed to absorb or camouflage
17 the proposed line. The in-depth inventory and
18 analysis of landscaping components and the visitor's
19 experience was imperative to the consultant's
20 ability to interact with the computer during the
21 alignment stage. As well, the use of computers
22 meant that many center line refinements could be
23 made in a relatively short period of time, rather
24 than a static approach to alignment design and
25 evaluation. We also participated with C. P. Rail
26 engineers in active process with the computer.
27 This ensured that the final alignment was truly
28 a cooperative effort, combining visual mitigative
29 measures and high quality engineering design.
30

1 (MacGregor)

2 Parks Canada representatives also
3 provided important and constructive input during
4 the design process. Their observations on the
5 fourth alignment was incorporated into the fifth
6 design alignment and contributed significantly
7 to its final quality.

8 In summary then, the design of the
9 new track was carried out in a spirit of cooperation
10 and respect for the visual environmental reclamation
11 and engineering requirements. The interaction
12 of the various disciplines from C. P. Rail, Parks
13 Canada and the consultants assured that the
14 proposed design would have the least possible visual
15 impact.

16 The visual impact assessment
17 consisted of four phases outlined in this slide.
18 The first two established a comprehensive appreciation
19 of the visual environment and the visitor's
20 perception of the Beaver Valley. The last two
21 phases applied that understanding to generate
22 design proposals with the C. P. Rail engineering
23 staff.

24 The four phases are noted as
25 follows:

26 Phase 1: the visual resource
27 inventory and analysis;

28 Phase 2: the synthesis evaluation
29 and determination of the visual absorption capability.
30

(MacGregor)

Phase 3: included the evaluation of the various alternative designs,

Phase 4: resulted in the proposed design itself.

Time limitations do not permit us to go into a detailed description of all the features that we have inventoried and analysed but the following slides will give you an indication of our comprehensive inquiry.

We firstly defined the Valley in its regional context from the point of view of the eastbound and westbound traffic in terms of its visual landscape units and finally we divided the Valley into its landscape components. Firstly, we looked at the landscape elements. All of those static elements, or all of those static objects rather, or voids in the landscape. We then looked at the landscape dynamics for those features that are always changing with respect to the movement of the park visitor travelling through the Park in their car, and finally we looked at landscape perception, which results from the visitor's behavioural environment, be it cultural, historical or social.

While landscape elements and dynamics are fairly easy to understand, I think perhaps a brief explanation of the different ways a Park visitor may perceive this new track is important.

(MacGregor)

The Park is a unique and scenic and physical environment and locating a railway in this environment may be considered as an intrusion into this semi-wilderness area. However, knowing that the Valley was first opened by the railway and subsequently became a National Park alters some people's perception of the relationship between the railway and the landscape. Therefore, the Beaver Valley will be perceived by many visitors as an important and necessary rail transportation link between central Canada's resources and its west coast markets and distribution points.

From this point of view the Beaver River Valley becomes a site of national importance to the Canadian economy and contributes to the standard of living of each Canadian. As we can see there can be a complete spectrum of attitudes to this second new proposed line.

Following this inventory 11 key observation points were located. These visually sensitive areas included five westbound views, for instance from Heather Hill; three westbound views, such as from Connaught Hill; three important viewpoints, including the Park entrance lookout, the Beaver Marsh and Stoney Creek.

A visual absorption matrix criteria was then established. Based on our understanding of the visual environment, we were able to identify those criteria and thus have been able to assess

1 (MacGregor)

2 just how vulnerable the landscape was to modification.
3 This slide outlines these criteria.

4 We then applied these criteria
5 to each of the key observation points -- again those
6 very sensitive areas, to determine which ones were
7 the most important.

8 The synthesis and evaluation assessed
9 the importance of each of the 31 individual landscape
10 components as well as the impact of a proposed line
11 on them. Emphasis was placed on determining the
12 ability of each feature to detract from or augment
13 the visual vulnerability of the new line. Finally
14 an overall assessment of the visual absorption
15 capability of each key observation point in the
16 Beaver Valley view shed was made. This enabled
17 the consultants to flag those areas and views that
18 were the most sensitive.

19 It also became obvious that each
20 landscape component individually contributes
21 to the integration of the railway into the
22 environment, and together they work in harmony
23 to minimize the visual vulnerability of the landscape.
24 The synthesis suggested that the Beaver Valley
25 is a complex and diverse natural system and that
26 this complexity directly and positively affects
27 its ability to absorb or fit the railway into the
28 environment.

29 In particular, the results of the
30 visual absorption capability matrix clearly

(MacGregor)

1 indicate that the Beaver Valley has a high to
2 moderately high capability of absorbing the track.

3 I will not go into the details
4 of this procedure or discuss the research that
5 is behind it at this point, but I do suggest that
6 you take a look at the exhibit panels where the
7 matrix is presented.

8 Before beginning design of the
9 surface route it was firstly necessary for C. P.
10 Rail engineers, the reclamation specialists and
11 the landscape architects to establish design
12 criteria. The following slide outlines these various
13 criteria.

14 Five different alignments for the
15 surface routes were proposed and evaluated, each
16 being a refinement of the preceding design.
17 Although the overall alignment was similar in all
18 cases, many significant adjustments were made to
19 solve engineering and visual impact problems.
20 The design process will be summarized in the next
21 five steps.

22 Firstly, with alignment number one, we
23 flagged the areas of significant disturbance for
24 serious concern and recommendations were made to
25 minimize their impact. On the second alignment we
26 took the recommendations into consideration and
27 generated new cross-sections as well as computer
28 graphic simulations of the priority areas. On
29 alignment number three, we improved upon number two
30

1 (MacGregor)
2 and added retaining walls and bridge structures.
3 Prospectives were generated from each key
4 observation point and overlaid on the black and
5 white photographs which you find in the Green
6 Book. Alignment number four involved the
7 participation of Parks Canada in a four-day work-
8 shop. Park staff identified several concerns
9 and the alignment was adjusted and improved when
10 possible.

11 Finally the comments from the
12 fourth alignment were incorporated to a fifth
13 alignment, which became the proposed design.
14 Prospective views of the proposed alignment were
15 generated using C. P. Rail's data processing
16 and plotting capabilities. These drawings were
17 then applied to photographs taken from the various
18 key observations points. In fact, these are the
19 same drawings that we use on the display panels
20 and which I will now use to describe the proposed
21 design.

22 As I have frequently mentioned
23 this proposed alignment is as a result of the
24 interactive design and evaluation process.
25 Various engineering, environmental reclamation and
26 visual concerns were balanced against each other
27 to yield the best possible solution.

28 The engineering requirements for
29 the nine-mile surface route included a maximum
30

1 (MacGregor)

2 grade of one per cent, a maximum curvature
3 of six degrees, a balance of cut and fills along
4 the route and provision of adequate clearance
5 of stream crossings. Other engineering constraints
6 were created by steep slopes and unstable soils.

7 Visual concerns centered around
8 the reduction of the size of cuts and fills in
9 areas visible from the highway, while reclamation
10 stressed the establishment of an erosion controlling
11 cover and the reintegration of the disturbed sites
12 into the natural successional processes. In some
13 cases significant adverse visual impacts resulted
14 in major changes to the proposed design. In many
15 areas only a small adjustment was necessary while
16 in a few locations engineering or visual
17 constraints were so severe that only minor changes
18 could be made.

19 I would now like to walk you down
20 the surface route and through the use of these
21 slides give you a description of what the final
22 design will look like to the traveller on the Trans
23 Canada highway. For graphic purposes, you will
24 note that the disturbed areas are shown in dark
25 brown -- of course, you will see that better if
26 you approach the panel. However, in reality after
27 Mr. Polster is finished with the reclamation
28 treatment, it will be a colour and a texture that
29 is more compatible with the natural environment.
30

(MacGregor)

I will treat this description by various sections frequently referring to the chainages that are marked on the slides. To begin with, we have the section from Rogers Siding to the Park boundary. This is just outside the limits of the photograph. From chainage zero to approximately 70, the line will be built on relatively flat terrain and will not be seen from any of the key observation points, because it is well screened behind coniferous trees.

From chainage 70 to the Park boundary, which is this line right here, we find that the Beaver River is near the base of the Hermit Range and up against the mountain side. The existing main line has been carved into the steep and rocky terrain just above the river. These physical constraints mean that the proposed line must therefore be squeezed between the Beaver River and the existing mainline necessitating rock cuts and the relocation of the existing line.

The cuts will be relatively large but there seems to be no alternative since the only other solution would be to relocate sections of the Beaver River and the placement of several large fills into the channel, into the river channel, which you can see just below. This would, of course have a much greater visual and environmental impact.

Although we recognize that

(MacGregor)

1
2 this section will be very visible from
3 the two viewpoints on the Heather Hill, that
4 is the viewpoint within the park and just outside
5 the park, there is little that can be reasonably
6 done to reduce the visual impact. However, the
7 application of an asphalt emulsion plus the
8 reclamation of the grade will greatly contribute
9 to camouflaging the rocks and the cuts and
10 consequently minimizing the visual impacts.

11 Looking at the park boundary
12 to Mountain Creek, in this section the flanks of
13 the Hermit Range are cut by the Mountain Creek
14 Valley, which you can see cutting through here.
15 The proposed alignment will run along the base of
16 the mountain slope and then across the Mountain
17 Creek fan, and you can basically see the Mountain
18 Creek fan coming out here. Although this area
19 is very visible from the Heather Hill viewpoint,
20 potential adverse visual impacts will be reduced
21 since the proposed alignment has been designed
22 primarily on fills, thus reducing the number
23 of more visible cuts. As a result most of the
24 line will be hidden by the existing tall conifers.
25 Nevertheless, some of the cut slopes will be
26 visible as a subtle line that marks the clearing
27 in the trees, much like the existing line.

28 For Mountain Creek to the Mountain
29 Creek Terrace, which is this dark spot right here,
30 the design was constrained by first of all two

(MacGregor)

1 requirements, which Mr. Fox mentioned yesterday.
2 Firstly there was the need to keep the line as
3 far away from the Mountain Creek campground as possible
4 secondly to minimize the size of the fills in
5 the gullies in the sections between chainage 163
6 and 176 -- it is just beyond. It is unfortunately
7 hidden by this tree here, by moving the alignment up
8 slope in the terrace area.

9
10 The alignment through Mountain
11 Creek Terrace was considered acceptable because
12 there is an already existing cut-over area, which
13 you can see on this before construction photograph.
14 Dave Polster will provide details of the proposed
15 reclamation program for this area following our
16 presentation. However, we would like to make a
17 few observations.

18 The initial visual impact of this
19 section will be significant since it is directly
20 visible from the Heather viewpoint. So you can
21 see it right in line with the views from that
22 viewpoint as well as from the Trans Canada
23 highway, which is just behind where the photograph
24 was taken. However, the long term effect will
25 be much less than the existing cuts through
26 Mountain Creek, referring to these up here. The
27 slopes will be flatter than the existing cuts
28 and consequently make them easier to rehabilitate.
29 As well the area will be given a high quality
30 reclamation treatment, including a top dressing

(MacGregor)

1 of suitable soil and the use of more mature plant
2 materials, probably in the range of six to seven
3 feet high, in addition to the regular planting of
4 trees and shrubs. Within a few years the terrace
5 will appear as a densely planted and textured
6 landscape similar to the vegetation in the
7 avalanche paths. In the long term it will, of
8 course, be totally integrated into the environment.
9

10 To screen the camp ground from
11 visual contact and the effects of noise, a large
12 berm will be constructed in this area. This
13 will be an attractive land form and designed
14 in an organic way to fit into the natural
15 environment. Further down the line, C. P. Rail
16 will build retaining walls to keep the size of the
17 cut slopes to a minimum.

18 For Mountain Creek Terrace to
19 Griffith Slide, the proposed line will cross the
20 moderately steep side slopes and relatively shallow
21 soils. However, visibility from these cuts is very
22 low. This section is less visible for two
23 reasons. Directly across the Valley, and you can
24 see the Trans Canada highway in red, directly
25 across the Valley tall conifers flank the highway
26 along here, and, of course, this is solid vegetation
27 between here and here, and the Heather Hill viewpoint
28 is more than a mile away. So views from there
29 are both distant and oblique.
30

(MacGregor)

1 In the Griffith and unnamed
2 slide areas, the engineering requirements dictate
3 that fills rather than cuts be used in this area to
4 ensure a stable track bed as was mentioned yesterday.
5 This approach also satisfies the visual design criteria
6 since fills are easier to hide behind the vegetation
7 than cuts. Nevertheless, this section is less
8 visible than most because tall conifers are
9 located adjacent to the highway and Heather Hill
10 is almost two miles away, the Heather Hill viewpoint.
11 All views, therefore, to the disturbed area will
12 be both distant and oblique or almost hidden.
13

14 Between the unnamed slide and
15 Raspberry Creek, bedrock is generally very close
16 to the surface. The design calls for relatively
17 small cuts in the rocks since the steep slopes
18 would result in large fills and the loss of
19 considerable vegetation. The exposed rock will
20 be treated with an asphalt emulsion to darken its
21 colour and small retaining bin walls will be used
22 to prevent any unnecessary vegetation removal at the top of
23 the slope. In any case, most of this section is not
24 visible since tall conifers along the highway block
25 most of the view. The Heather Hill viewpoint is
26 more than three miles away and most of the
27 views from there are screened by 80-foot high
28 trees adjacent to the surface route.
29
30

(MacGregor)

1
2 Between Raspberry Creek and the
3 wetslide area, the flanks of the Hermit Range
4 are steep, somewhat irregular and cut by several
5 creeks and avalanche paths. In response to the
6 increasing irregular terrain and the need to build
7 a 9,000-foot long siding, the design calls for
8 numerous large cuts and fills. Large fills will
9 be required to construct the line across Surprise
10 Creek at a sufficient elevation to clear the
11 Creek, and several major cuts and fills will be
12 constructed at the creek and avalanche paths.

13 This section of the line will be
14 more visible than most of the previous sections because
15 the terrain is steep and there is less foreground
16 vegetation to provide screening. As you can see
17 there is little foreground in this area. As well
18 there are more opportunities to view the area as
19 seen in this photograph from the highway pull-off.
20 Nevertheless, through numerous alignment
21 modifications we have tried to minimize the more
22 visible cuts. Also this area has the
23 most extensive use of retaining walls. Approximately,
24 4,000 linear feet will be installed to minimize the
25 extent of cuts.

26 Retaining walls would also be
27 built of exposed aggregate or textured concrete
28 or possibly sprayed with asphalt emulsion to harmonize
29 the colour with the existing environment. As well,
30 the planting of natural grasses, trees and shrubs

(MacGregor)

1 in the area, as Mr. Polster will outline later,
2 will restore the native colour and texture to the
3 cuts and fill slopes and enable them to blend into
4 the natural environment.

5
6 Between the wet slide area and
7 Stoney Creek, the forested slopes of the Hermit
8 Range are steep and irregular. This is one of the
9 most visible sections of the surface route.
10 In recognition of the potential for serious
11 visual impacts several major changes were made
12 during the design process. Fills were emphasized
13 as much as possible to reduce the number of more visible
14 cuts. In areas where screening vegetation was
15 sparse or would be destroyed by conventional cut and fill
16 construction, the design called for a bridge structure
17 at Stoney Creek as well as 1200 linear feet of
18 retaining walls.

19 To build a stable line across the
20 wet slide area, the cuts and fills will be flattened
21 2 to 1. This will facilitate the task of
22 reclaiming the area. In order to reduce the size
23 of the cuts required beyond the wet slide area,
24 retaining walls of dark concrete will be built on
25 both up slope and down slope sides of the line to
26 protect the existing vegetation. Approximately 700
27 feet of bridge structure will also be built to
28 prevent large fills that would have been created
29 in order to get the line across the large gully
30 preceding Stoney Creek. Reclamation vegetation

1 (MacGregor)

2 along the Trans Canada highway.

3 Finally the east portal of the short
4 tunnel will be in tall trees above the highway and
5 will not be visible from the road.

6 In conclusion I have attempted to
7 give a visual description of what the line will
8 look like soon after construction. I have
9 emphasized that large cuts and fills at Mountain
10 Creek Terrace, Raspberry Creek, the wet slide
11 area, the avalanche paths and Stoney Creek will
12 be treated with retaining walls and an intensive
13 reclamation program. Other areas that are not
14 so visible nevertheless will also be completely
15 revegetated immediately after construction in order
16 to prevent erosion. Within a few years after
17 construction the line will be perceived as a dark
18 green band, wider, but in many ways similar to the
19 existing line that now crosses the lower face of
20 the Hermit Range.

21 I would like to terminate my
22 presentation with a brief outline of the various
23 design parameters or mitigative measures that
24 are meant to assume a reasonable and acceptable
25 integration of the new lines into the visual
26 environment of the Beaver River Valley.

9

10

11

12

13

14

15

The first one is of course alignment changes and I have already discussed that many times. These were the changes that were made during the design process to minimize cuts and fills and to of course protect existing vegetation. Number 2 is the use of retaining walls. Approximately 100,000 square feet of retaining walls has been used especially to minimize the extensive cuts and consequently, the removal of upslope vegetation. They were also used on fills to protect trees when possible. Downslope walls will be reinforced earth or bin walls, and tied back walls will be used on the upslopes.

16

17

18

19

All visible retaining walls will be of exposed aggregate or sprayed with an asphalt emulsion to assume a dark grey colour that integrates into the environment.

20

21

22

23

24

25

26

27

28

29

30

Trestles and bridge structures. A 700 foot long structure will be used in the Stoney Creek fan area. North of the creek a very special and incidentally costly effort has been made to eliminate the large fills that would have resulted under the normal construction techniques at Stoney Creek. The addition of this less intrusive bridge structure therefore represents a significant effort to protect the visual resources of this sensitive area. Of course, the 6,700 foot trestle will also have a similar impact.

B-2

1 (MacGregor)

2 Earth barriers at the Mountain Creek
3 terrace. The proposed alignment passes within a few
4 hundred feet of the Mountain Creek campground. It is
5 therefore proposed to construct a 20 foot berm between
6 the campground and the new track. The shape of this
7 800 foot long land form will be natural and reflect
8 the gentle rolling land forms of the area. The berm
9 will be landscaped with local vegetation; as I
10 mentioned the renaturalization will be with between
11 five and six foot high trees.

12 As well all edges at the limits of
13 the cuts and fills will be rounded off to prevent
14 sluffing and to create a landscape form that is
15 more natural.

16 I have made frequent references to
17 reclamation, as it will represent the most major
18 effort to enable a successful integration of the
19 proposed line into the visual environment, and Mr.
20 Polster will be following our presentation with more
21 details.

22 However, I would like to emphasize
23 a few points. Firstly, vegetation planting layouts
24 will have an organic or natural form to blend into
25 the existing environment. Secondly, renaturalization
26 will start immediately after construction. As well,
27 areas of high visibility will receive the most
28 attention, that is, native trees will be used to
29 recreate an instant landscape effect, and finally,
30

B-3

1 (MacGregor)

2 asphalt emulsions have been proposed on exposed rock
3 cuts as a one shot application to minimize the visual
4 impact of the high contrast rock in the few years
5 after construction. Following that renaturalization
6 will establish the conditions to its former
7 situation.

8 Finally, a responsive monitoring
9 program has been set up by C.P. Rail to ensure its
10 commitment to the protection and revegetation of
11 the Park landscape. Professional landscape
12 architects and reclamation specialists will be on
13 site during the various phases of the construction
14 and their responsibilities will include firstly
15 responding to unforeseen circumstances, assisting in
16 the location of retaining walls, determining the
17 exact landscape planting layouts, and of course
18 making regular reports to Parks Canada.

19 The monitoring program, as outlined
20 in the red book, is only a guideline and a more
21 definitive schedule will have to be coordinated with
22 the contractor.

23 In conclusion, it has been assessed
24 that the new line will have a definite and permanent
25 visual impact on the Beaver River Valley. However,
26 after reclamation, the impact will not be significantly
27 greater than the existing line. All efforts were
28 made at the design stage to minimize the disturbance
29 to the landscape and to protect existing vegetation.
30

B-4

1 (MacGregor)

2 That consciousness will be maintained
3 throughout the construction phase and assured by
4 a monitoring program.

5 We trust that the visual impact
6 assessment document and the exhibit panels clearly
7 indicate these intentions. Thank you.

8 I will now ask Mr. Haggerstone to
9 present the ventilation shaft.

1 (Haggerstone)

2 shaft structure is over 200 feet wide, about 400 feet
3 long and surrounded by trees that range from 65 to
4 more than 80 feet in height. That is this clearing.

5 The structure itself will be
6 about 300 feet long and 100 feet wide. Although the
7 maximum height of the two vent stacks above natural
8 ground level will be 80 feet, the majority of the
9 building will be less than 60 feet tall.

10 Visuals impacts were assessed for
11 visitors travelling the highway as well for those
12 stopped at viewpoints. However, recognizing that
13 visitors outside their vehicles will be more aware
14 of the landscape than those driving by, we concentrate
15 our assessment efforts on the viewpoints.

16 Views from the two major locations
17 where visitors leave their vehicles -- the Glacier
18 Park Lodge and the Summit Monument, again just behind
19 the trees -- were assessed in considerable detail.

20 The third location that was studied
21 in depth was the start of the vent shaft access road,
22 right about there. Although not a viewpoint and
23 located on a curve on a hill where there are three
24 lanes of traffic and no provisions for parking, it
25 is the closest approach to the vent shaft structure
26 for highway users.

27 The studies were conducted in several
28 stages. C.P. Rail field staff conducted ground
29 surveys to measure the heights of the trees around
30

B-7

1 (Haggerstone)

2 the clearing for the vent shaft structure, and to
3 determine the elevation of the test site and its
4 location with respect to siting of the structure.
5 I will refer to this test site in a moment.

6 The elevations of tops of some of
7 the surrounding trees and some of the key points on
8 the structure are shown in this true scale cross-
9 section. The vent shaft structure is here; the
10 elevations in feet above sea level of the tops of
11 the trees and the bases of the trees, and the location
12 of the highway and a viewer are shown in this
13 section. This is one of the panels that is in the
14 room.

15 Red helium-filled balloons were tied
16 in the clearing at the height of the tops of the
17 vent stacks. The string of balloons here is ten
18 feet from top to bottom. The balloons are about
19 a foot and a half to two feet in diameter. The
20 line has been marked in ten foot increments, and
21 unfortunately with the lighting we cannot see them,
22 but I had marked on this line with red survey flagging
23 every ten foot increment.

24 To reduce the possible effects of
25 wind, the balloons were guyed on three corners to
26 reduce their movement and the studies were conducted
27 very early in the morning on a relatively calm day.

28 The area was then observed from the
29 highway and the viewpoints to determine the locations
30

B-2

1 (Haggerstone)

2 from which the structure might be seen, and here
3 peaking just through the gap in the tops of the trees
4 right at the tip of the arrow is the top of one of
5 those balloons. In this photograph the balloon is
6 just visible.

7 Perspective drawings of the vent
8 shaft structure, as it would appear from selected
9 observation points were then prepared using C.P.
10 Rail's computer systems in Calgary.

11 These perspective views were
12 combined with photographs to simulate the actual
13 location of the building in the landscape. This
14 may not be perceptible to people in the back, but
15 that line drawing that I previously showed has been
16 superimposed on this photograph and you can see the
17 outline of it here. This is the location of the
18 balloon for reference purposes.

19 This computer graphi photomontage
20 was then used to estimate the portions of the tops of
21 the vent stacks that could be visible, here shown
22 in grey. Note the location of the balloon for
23 reference.

24 Our assessment of the possible
25 visual impacts on visitors at viewpoints dealt with
26 views from the Glacier Park Lodge and the Summit
27 Monument. The existing clearing was not visible from
28 just outside the dining room window of the Glacier
29 Park Lodge, which is where this photograph was taken.
30

B-9

1 (Haggerstone)

2 This is the recently constructed
3 Parks Canada Interpretative Center. The ventilation
4 shaft structure, were it visible, would sit in about
5 that location. The balloons were barely visible
6 through gaps through the tree tops, but they were
7 so small that they are not visible on the photograph.

8 This telephoto shot shows what
9 you would see if you used small binoculars. The
10 balloons were very slightly visible right at about
11 this location, but unfortunately again, they are
12 not visible on this particular slide.

13 The foreground vegetation comes very
14 close to blocking the view completely, and from
15 many locations near the hotel these balloons were
16 not visible. I might add here that I am at the
17 parking lot right outside the hotel at this point
18 and you can see those balloons just above the top
19 of the trees if you know where to look. However,
20 if you are down on the highway, these foreground
21 trees completely block that from view.

22 This computer graphic photomontage
23 shows where the building would sit in the landscape.
24 It shows where it would be in the forest. That is
25 the outline of the building there. The balloons are
26 virtually invisible. The existing clearing was not
27 visible at all from that point, and I again would
28 emphasize, that clearing is 400 feet long.

29 In this simulation, the grey represents
30

B-10

1 (Haggerstone)

2 the portions of the structure that could possibly be
3 visible. As you can see, it would be almost imperceptible
4 since it will be more than a mile away and the visible
5 portions of the tops of the stacks will appear very
6 small as a result of that distance.

7 The line of sight distance from the Summit
8 Monument to the vent shaft structure is approximately
9 half a mile. The existing clearing is not visible.
10 Now, I could not find it even when I knew where it
11 was. Now, Peter Holubar said he could see it, but
12 I could not.

13 The balloons are barely visible
14 through a gap in the tree tops, and I apologize
15 for the darkness of these slides but I had to do
16 this study about seven o'clock in the morning before
17 the winds picked up.

18 This photomontage shows the location
19 of the proposed structure in the forest, and I point
20 out again that these photographs are all on the panels
21 if you cannot see the details of them.

22 The existing clearing was not visible
23 to my eye from this location and I found the balloons
24 were barely visible through a gap again in the
25 tree tops.

26 This is the balloon again, for reference.
27 This is the view from the Summit Monument. In this
28 simulation, the light grey areas represent the
29 probable extent of the visual impact of the vent
30

B-11

1 (Haggerstone)

2 shaft structure on the view from the Summit
3 Monument. This grey area represents about a ten
4 foot segment of the top of the vent stacks. I should
5 point out that we have recommended that the building
6 be a dark, non-reflective green to further minimize
7 any visual impacts.

8 The trees in this area range in height
9 from 65 to more than 80 feet. The building design
10 is such that most of the structure will be hidden
11 from view, but portions of the top few feet of the
12 vent stacks could be visible through gaps between
13 the tree tops.

14 Mr. Chairman, I would like at this time
15 to call your attention to an error in the red book
16 on page 23 and maybe I could bring this up again
17 when we are reassembled. It refers to a couple of
18 words. Would you prefer that I brought this up when
19 we are back at the tables and you have the book?

20 THE CHAIRMAN: You might as well
21 mention it now.

22 MR. HAGGERSTONE: The last sentence,
23 the word "is" should be replaced by "could be" and
24 the word "tall" should be replaced by "shorter".
25 The sentence should read: "Only a few feet of the
26 structure could be visible above the shorter trees."
27 The key words were "is" and "tall".

28 This true scale cross-section along a
29 sight line from the Summit Monument shows how the
30

E-12

1 (Haggerstone)

2 trees will screen almost all of the building from
3 view. Note that the structure will not be visible
4 if some of the taller trees happen to stand between
5 it and the observer. This tree right here, for
6 example, is taller than the top of that building if
7 you are standing there.

8 While at the Summit Monument, I found
9 that due to these variations in the tree height, from
10 some places I could see my balloons and from other
11 places I could not as I walked around, and as I
12 moved around it was visible and not visible.

13 To assess the possible visual impacts
14 on visitors driving through Rogers Pass, we first
15 considered the eastbound travellers, people who would
16 be approaching the Pass from the west, coming up the
17 hill into Rogers Pass.

18 Views of the site from the bottom of the
19 hill leading to the pass blocked by the southeast
20 ridge of Mount Cheops. From this location, the
21 shoulder of this mountain blocked the view. From part-
22 way up the hill, the views were blocked by the
23 lower slopes of Avalanche Crest. From this location
24 here, views were blocked by the terrain.

25 For the rest of the climb into the Pass,
26 the views were blocked by dense stands of 65 to 80
27 foot tall coniferous trees that line the highway,
28 these trees here. The sight distance from the start
29 of the access road to the structure itself will be
30

B-13

1 (Haggerstone)

2 about 1200 feet, slightly less than a quarter of a
3 mile. The exception to that blocking is the clearing
4 at the entrance to the access road to the vent shaft.

5 From this access road to the vent shaft,
6 the existing clearing is not visible. The top balloon
7 is just visible here through a gap in the tree tops.

8 In this photomontage that I showed
9 before shows the location of that building in the
10 forest, and the light grey areas show the portions
11 of the building that would be visible from that
12 location -- could be visible from that location.

13 This true scale cross-section along a
14 sight line from the start of the access road shows
15 how the trees will screen almost all of the building
16 from view. As the trees continue to grow, this
17 foreground screening will of course become even
18 more effective.

19 The most important consideration is
20 that few people will view the structure from this
21 location since it is on a curve near the top of
22 a hill, as I pointed out previously.

23 We concluded that, with the exception
24 of a brief glimpse through the clearing at the start
25 of the access road, the vent structure will not be
26 visible to eastbound highway travellers approaching
27 the summit of Rogers Pass.

28 Westbound travellers coming from this
29 direction, coming from Calgary enroute to Vancouver,
30

B-14 1 (Haggerstone)

2 might see small portions of the tops of the vent
3 stacks from the short stretch of highway between the
4 Glacier Park Lodge and the Summit Monument. Around
5 this corner from about here to the Summit
6 Monument you may get small glimpses similar to the
7 views from the Glacier Park Lodge.

8 However, the visual impacts will be
9 minimal since the visible portions of the structure
10 will appear very small, there are scattered clumps
11 of trees that block the view in some locations along
12 the highway here, and most of the viewers will be
13 in moving vehicles with their attention directed
14 down the highway rather than along the side of the
15 mountain.

16 In summary then, our study revealed that, one
17 when viewed from the Glacier Park Lodge, the ventilation
18 shaft structure will be virtually imperceptible;
19 two, the visual impact of the structure on the view
20 from the Summit Monument will be small; three,
21 the vent shaft structure will not be visible from
22 any point along the highway west of the access road;
23 four, the visual impact of the vent shaft structure
24 on the view from the start of the access road will be
25 minimal; five, the visual impact on travellers
26 westbound from the Glacier Park Lodge will also
27 be minimal; and six, the screening provided by
28 vegetation is essential in minimizing the visual
29 impacts and as these trees continue to grow, the

screening in all areas will become even more effective,
barring of course the spruce park beetle or whatever
it was we heard about.

That is the end of my presentation.

I would now like to turn it over to Mr. Dave
Polster.

B-16

1 (Polster)

2 MR. DAVE POLSTER (Norelco): Mr.
3 Chairman, members of the Panel, ladies and gentlemen,
4 I would like to present a brief overview of the
5 reclamation program proposed for the grade revision
6 through Rogers Pass. Inasmuch as the task of
7 reclamation for this project is going to be a major
8 undertaking, I would like to outline the major
9 components of the program. I will present the
10 detailed plans and contingencies for two major cuts
11 and fills as examples.

12 Specific program details for the grade
13 have been included in the brief prepared for these
14 meetings, and I trust you have had an opportunity to
15 review these. I will be pleased to answer any of your
16 questions in regard to the conduct of the
17 reclamation work during the question period.

18 The reclamation plans for the surface
19 grade have been developed with input from the
20 visual impact assessment, the biophysical studies
21 and the engineering studies. The plans outline the
22 procedures which we will be using to conduct the
23 reclamation work. We fully expect to have input
24 from a range of specialists during the conduct of
25 the work. This diagram illustrates the inter-
26 relationships of disciplines.

27 The reclamation program has been
28 designed to harmonize with the surrounding landscape.
29 I will digress briefly to give you an overview of those
30

E-17

1 (Polster)

2 features of the terrain, natural vegetation and
3 successional patterns which were integrated into
4 the reclamation plans. As the major part of the
5 reclamation program will be conducted in the Beaver
6 Valley, I will be speaking primarily of this
7 area. I will touch briefly on those aspects of the
8 vent shaft site and the west portal area which are
9 important to the successful reclamation of
10 these sites.

11 The surface grade will run along the
12 lower slopes of the Beaver Valley. Natural slopes
13 in the area are generally steep. The vegetation
14 cover is a mixture of late to mid seral forests of
15 western hemlock, Engelmann spruce, western white
16 pine, subalpine fir, lodgepole pine, Douglas fir,
17 western red cedar, aspen and cottonwood. These
18 forests are broken by several avalanche tracks. Bogs
19 occur on the valley bottom while narrow bands of
20 alluvial vegetation occur along the streams. Grass-
21 lands do not occur in the area although herbaceous
22 meadows are associated with the avalanche tracks.
23 Shrubs such as alder, red osier dogwood, thimbleberry
24 and willows as well as trees such as aspen,
25 cottonwood and paper birch play an important role as
26 early successional species. In some cases the shrub
27 stage of the successional forest is skipped entirely
28 and hemlock, cedar and subalpine fir invade
29 disturbed sites directly. I would like you to keep
30

B-18

1 (Polster)

2 these various successional stages in mind as I go
3 through the reclamation plan.

4 Two major objectives have been
5 developed for the reclamation program. The first
6 being the revegetation of exposed erodible
7 materials to minimize erosion and subsequent water
8 quality degradation; the second being the
9 amelioration of the visual impacts of cuts and fills
10 through the use of vegetation.

11 In addition, two subsidiary objectives
12 have been developed which follows from the major
13 objectives. The first one being the establishment
14 of a self-sustaining vegetation cover which is
15 compatible with the naturally occurring vegetation
16 in the area; and the use of species native to the
17 Park where this does not compromise the other
18 objectives.

19 There are four major components of the
20 reclamation program: Development of a suitable
21 rooting medium and seed bed for germination;
22 establishment of an erosion controlling grass/legume
23 cover; establishment of a permanent cover of woody
24 species; and the maintenance of the reclaimed sites
25 to ensure success.

26 I will briefly outline these aspects of
27 the program, after which I will describe as examples
28 how these will be pulled together to reclaim two
29 of the major cuts and fills.
30

B-19

1 (Polster)

2 The development of a substrate which
3 will sustain plant growth is critical to the success
4 fo the reclamation program. A program of top dressing
5 those materials with a low suitability for plant
6 growth was developed in order to provide suitable
7 growth media for the revegetation species.

8 I will briefly outline the procedures
9 used in the development of this aspect of the
10 reclamation program.

11 The surface grade was initially sub-
12 divided into about 40 landform units by Thurber
13 Consultants. We heard about this yesterday. These
14 units formed the basis for assessment of reclamation
15 suitability. Reclamation suitability was
16 assessed primarily on the basis of texture,
17 although the nutrient status of the various materials
18 was also assessed. Three classes of reclamation
19 suitability were used: high, moderate and low.
20 Materials with high and moderate suitability can be
21 used as top dressing, while the low suitability
22 materials should themselves be topped dressed.

23 Tables were prepared outlining which
24 materials should be salvaged for use as top dressing
25 and which sites will require a top dressing. Detailed
26 plans have been developed for determining mass hauls,
27 schedules and how construction will proceed. Top
28 dressing salvage and disposition was one of the many
29 factors considered in the development of these plans.
30

B-20

1 (Polster)

2 We recognize that care will be required
3 to ensure that the top dressing program is conducted
4 in a manner which will provide the best possible
5 growth medium for the revegetation species.

6 The next phase of the reclamation program
7 following establishment of a suitable growth medium
8 will be to prepare the sites to receive the initial
9 seed and fertilizer. The major aim of site
10 preparation is to break up any surface crusting which
11 has developed and to provide a loose surface which
12 will catch the seed and fertilizer and provide
13 sites suitable for germination. A number of methods
14 have been used for preparing industrial sites for
15 reclamation. Floating pipestem harrows, clodbusters,
16 which are like spiked chains, and teeth on backhoe
17 buckets have all been used for preparing seed beds.
18 Frost action also serves to loosen the soil surface.
19 We expect that we will use a variety of methods
20 for preparing the seed bed, depending on the site.

21 In order to ensure erosion is
22 minimized and a green colour is rapidly established,
23 we propose to develop a grass/legume stand on the
24 disturbed sites as an initial cover. This will be
25 established from seed after preparing the seed bed.
26 We plan to use two methods for seeding: broadcast
27 and hydroseeding, depending on the site.

28 Broadcast seeding, where seed and
29 fertilizer are spread dry either from handheld seeders
30

B-21

1 (Polster)

2 or from helicopters, will be used in most cases.
3 However, hydroseeding where seed and fertilizer
4 are spread in a slurry with water and mulch, will
5 be used in cases where there are mixed bedrock and
6 soil slopes, where the materials are expected to be
7 particularly susceptible to erosion, or in situations
8 where broadcast seeding would not be as effective.

9 Seeding methods will be determined on a
10 site specific basis. I have outlined general choices
11 in the brief.

12 The seed mixes we have selected have been
13 designed to provide an optimum cover rapidly. The
14 seed mixes have been balanced to provide the
15 percentage of pure living seed listed in the percent
16 by species composition column. Percent by weight is
17 given so that the seeds can be ordered directly from
18 the seed dealers. I would like to point out several
19 aspects of seed purchase which may help to allay
20 any fears which may exist with regard to seed.

21 First of all, the seeds which are used
22 in the mixes will be Canada No. 1 grade or better.
23 This will reduce the possibility of introducing weed
24 species. Also, it makes economic sense to use the
25 best seed available, as the cost of seed is small
26 in relation to other reclamation costs, just as you
27 would not buy a fancy Porsche and then put cheap
28 recaps on it. I should also point out that all
29 legumes will be inoculated with the appropriate
30

B-22

1 (Polster)

2 nitrogen fixing bacteria.

3 We will be fertilizing the reclamation
4 sites for establishment of the initial cover. We may
5 apply the potassium and phosphate just prior to
6 site preparation work to incorporate it into the
7 growth media. Soil samples will be collected and
8 analyzed to determine the appropriate fertilizer
9 application.

25
26
27
28
29
30

1 (Polster)

2 As with seed it does not make much sense to
3 scrimp on the fertilizer although care must be taken
4 not to apply too much.

5 As I mentioned earlier, one of the
6 objectives of the reclamation program is the esta-
7 blishment of a permanent vegetation cover. We
8 feel that the best way to ensure that we have a
9 permanent cover is to re-integrate the disturbed
10 sites into the natural successional processes which
11 occur in the Park. For this reason we will be
12 planting early successional species such as alder
13 and cottonwood as well as climax species such
14 as hemlock, cedar, spruce and fire.

15 Planting patterns have been
16 designed to harmonize with the surrounding vegetation
17 as much as possible, although we will not be
18 planting trees near the tracks as they would only
19 have to be removed a few years down the road.
20 Detailed planting designs were prepared for a number of
21 sites along the new grade. These incorporate the
22 criteria set out by the landscape architect
23 to reduce the visual impacts. For the most part
24 we plan to use container grown stock. However,
25 in some areas, such as through the Mountain Creek
26 gravel pit, we will be using larger stock so that
27 the visual impacts are minimized as quickly as
28 possible.

29 We will be initiating seed
30

1 (Polster)

2 collections this year in order to ensure we have
3 stock available for the spring of 1985 when we plan
4 to be doing our first plantings.

5 The final Phase of the reclamation
6 program will be the maintenance of the reclaimed
7 areas. Although the program has been designed to
8 minimize the need for maintenance, we expect
9 there will be some situations where maintenance such
10 as re-fertilization, re-seeding or re-planting of
11 trees and shrubs will be needed to achieve the
12 desired reclamation results. The maintenance
13 program will also ensure that problem sites, such
14 as erosion gullies do not have a chance to get
15 firmly established but are repaired quickly.
16 We feel that by properly attending to any problem
17 sites which develop we will be able to minimize
18 the adverse effects on both the visual and
19 biological environment.

20 I would like to discuss surface erosion
21 for a moment so we get this aspect of the job into
22 proper perspective. Erosion rate of from 45 to
23 90 tons per acre have been reported in the literature
24 for logging roads in B. C. and Oregon. Rates of
25 up to several hundred tons per acre have been
26 reported for highway cuts in the U. S. We expect
27 the erosion rate for the new grade to be less than
28 this range as we will be implementing measures such
29 as immediate revegetation to reduce erosion.
30

(Polster)

1
2 I should also point out that the
3 side slopes on the new grade will be as steep
4 as those of the existing access road which are
5 comparable to the typical logging roads. In any
6 case, we will be monitoring erosion rates closely
7 and can apply additional measures as required.
8 We will be using a rill meter and following
9 procedures set out in the literature for these
10 erosion measurements.

11
12 Now that I have outlined the
13 general procedures we will be using, I would like
14 to describe how these will be applied in two
15 specific examples. I have purposely chosen two
16 of the most sensitive sites. Although we do not
17 have time during these hearings to go through
18 the entire line in detail, I hope you will see
19 the ways in which we will be approaching the
20 reclamation of the cuts and fills along the grade
21 through these examples.

22 My first example is the Mountain
23 Creek Pit cut. As you are aware, the new grade
24 will traverse the existing Mountain Creek Pit
25 resulting in a large cut. James MacGregor has
26 explained how this cut will be a visual impact when
27 viewed from Heather Hill. By working with James we
28 have developed a reclamation design which will
29 minimize this impact.
30

1 (Polster)

2 Let me begin by explaining how we
3 expect this cut will be constructed, as I think
4 it is important to have an understanding of the
5 construction methods in order to appreciate how we
6 have dove-tailed the reclamation with the
7 construction.

8 First of all, the upper limits of the
9 cut will be surveyed and flagged. Clearing crews
10 will then remove the vegetation and the site
11 will be grubbed to remove the roots and stumps.
12 A tote road would then be constructed along the
13 top of the cut. This would be to allow access for
14 the scrapers. From this initial bench the material
15 would be cut with scrapers. A front-end loader
16 and trucks would be used if the material is to
17 be hauled a long distance, and this depends on
18 the construction mass balances.

19 In any case the results in terms
20 of the cut surface will be basically the same.
21 The rough cut surface will be developed in stages of
22 about 30 feet so that top dressing can be placed
23 on the cut while there is still access. The top
24 dressing will be hauled along the access bench
25 and dumped for placement with a backhoe. If the
26 top dressing material is too wet to spread
27 effectively, it will be left on the bench to dry
28 out. In any case, the rough cut slope will
29 not be smoothed so that the one to two foot
30

1 (Polster)

2 horizontal ridges which developed during the cutting
3 will remain to hold the top dressing on the slope.
4 A one foot layer of top dressing will be applied.
5 Further cutting of the slope can then continue.
6 The process will be basically a repeat of the one
7 I just outlined.

8
9 Now let us impose the seasonality of
10 construction on the whole process. Let us say we get
11 to the end of October and the construction season
12 is winding down. About one half of the slope
13 would be completed with the top dressing. I should
14 mention that when we have the backhoe operator
15 placing the top dressing on the slope, we will
16 get him to swing his bucket back and forth along
17 the slope so we get little horizontal ridges
18 on the top dressed slope. Anyway, in this case,
19 we would probably rely on frost action to ensure the
20 site is loose enough to allow the seed and
21 fertilizer to lodge. Seeding and fertilizing
22 would be conducted using a helicopter as it is
23 likely there will be a fair amount of area ready for
24 seeding throughout the entire surface route.

25 We would be using the dry site seed
26 mix in this case. Soil samples taken about one
27 month prior to the seeding and fertilizing
28 would be used to determine optimum fertilizing
29 rates. The seeding and fertilizing would complete
30 the reclamation of this site for that year.

(Polster)

Early the following spring, just after the snow leaves the site, the second phase of the reclamation program would begin. This would entail the planting of trees and shrubs as well as assessment of the condition of the slope to detect the presence of excess erosion, and this is when we would be monitoring with our rill meters. Because of the very visible nature of this site, we plan to use scattered clumps of larger trees as well as the standard planting of container grown stock. We plan to plant about five clumps of the larger trees with 10 to 20 trees in each clump per acre. These larger trees would have been collected and balled in the fall, prior to freeze-up, and stored in the sand near the site. The landscape architect would be on site during this phase of the work to ensure the plantings are done with maximum regard for amelioration of the visual impact.

The second year of construction would proceed in the same manner as the first. We expect that the cut will be completed down to the subgrade and that the noise berm would also be completed. The fall program would again entail seeding and fertilizing following in the spring by tree and shrub planting and site monitoring.

Let us look for a moment at what methods might be used in the event that the spring inspections turned up problem sites, such as

1
2 (Polster)

3 excess gullyng. Let us say we have a worst case
4 situation where there are erosion gulleys which
5 have cut through the top dressing material down
6 to the ground level material of the cut. It is
7 unrealistic to expect the gullies would extend
8 into the gravel for any distance. Anyways the
9 first stage of repair would consist of crews
10 on the site with hand tools to fill the gullies
11 and reshape the slope. This will be followed
12 by reseedng and fertilizing the reshaped gullies.
13 If we suspected that problems were likely to
14 reoccur, we would consider an application of
15 soil binding spray. It is recognized that this
16 procedure would be labour intensive, however,
17 short of getting a machine on the slope, which
18 risks disturbing the surrounding areas, there is
19 little else which could be done. We are prepared
20 to incur the expense of such hand work for the
21 benefit of rapid repair of problem site.

22 Monitoring of the site would
23 continue for several years after the reclamaton
24 is complete in order to ensure the vegetation was
25 firmly established.

26 My second example is the wet
27 slide area. The soil materials in this area
28 are suitable for plant growth. Therefore, top
29 dressing would not be applied. Also in order to
30 ensure due technical stability, slope angles have

1 (Polster)

2 been reduced to 2 to 1. This will allow machine
3 access across the site for site preparation.
4 Site preparation would consist of harrowing
5 across the slope with a pipestem harrow. This
6 will be followed by broadcast seeding using the
7 moist sites mix and fertilizing. Tree and shrub
8 planting in the spring would utilize moisture-
9 loving species such as cottonwood, cedar and
10 hemlock. Direct planting of unrooted willows,
11 red-ozier dogwood and cottonwood may be used
12 pending the results of work currently being done
13 at Lake Louise, and those results are quite
14 promising at present, but we will see how it goes.

15 This site has a greater potential
16 for surface erosion than most due to the deep
17 fine textured materials. We will be monitoring
18 the site closely to ensure that erosion does not
19 become a problem. Soil binding sprays and some
20 of the bioengineering techniques, which I will
21 be discussing shortly would be used if problems
22 developed.

23 I hope these examples give you an
24 idea of the reclamation we are planning. I should
25 point out that detailed plans, such as I have
26 shown, have been formulated for all of the major
27 cuts and fills. These are included in the reclamation
28 plan report.

29 I would like to take a few minutes
30 to outline some of the special reclamation

1 (Polster)

2 techniques which we plan to use to establish
3 vegetation in some of the more difficult sites.
4 Of particular importance are the areas adjacent
5 to water channels, steep side slopes along the
6 grade from Stoney Creek to the east portal of the
7 short tunnel, and areas where the soils are
8 particularly prone to erosion; that is, they are
9 silt areas. Most of the techniques I will be
10 discussing fall into the realm of bioengineering.
11 The practice of bioengineering is relatively well
12 established in Europe, however, there are only
13 a few examples of bioengineering in Western Canada,
14 one of which is in Glacier National Park.

15 Brush layering is a technique
16 which can be used to establish shrubby vegetation on
17 steep slopes. This method was used successfully
18 on the abutments of the recently constructed
19 avalanche shed near the Pass, where this photo
20 was taken. Living, unrooted cuttings of
21 willows were used in this case. However,
22 willows, cottonwood and red-osier dogwood would all
23 work. We would be using this technique near the
24 bridge abutments along the new grade. Hedge
25 brush layering is a similar technique but in
26 this case rooted shrubs are planted in with the
27 cuttings. Alder would be a prime species in the Rogers
28 Pass to include in a hedge brush layer.
29
30

(Polster)

1
2 Another bioengineering technique
3 called live pole drains could be used to provide
4 drainage on slopes. This technique uses bundles of
5 living cuttings placed in ditches and covered with
6 a thin layer of soil. The idea is that the water
7 flows through the bundle and eventually the
8 cuttings take root and grow, drawing moisture
9 from the soil by transpiration.

10 Soil binding sprays such as Deci 162,
11 which is a polyurea polyalkylene oxide can be used
12 to stabilize soil surface until vegetation can
13 be established. Although these materials
14 are relatively expensive, they can perform an
15 important function in certain circumstances.

16 In the same vein, soil holding
17 fabrics and meshes can be used to hold the soil
18 until vegetation can be established. We plan to
19 test the effectiveness of a variety of these techniques
20 this summer.

21 This brings up the topic of what
22 we are presently doing and planning in terms
23 of reclamation. As you are no doubt aware, we
24 initiated a program of reclamation testing a year
25 ago with the establishment of operational reclamation
26 trials on the slopes of the east cut at Mountain
27 Creek. The slope we selected comprises the most
28 challenging set of site conditions of any site
29 expected on the new grade. It is south facing and
30 therefore gets very hot in the summer. Soil surface

1 (Polster)

2 temperatures live up to a 130 degrees, it has
3 been mentioned. It is very steep, about 36
4 degrees or 1.35 to 1, steeper than any of the
5 slopes in the new grade. It is gravelly and
6 generally not a good place to try and get vegetation
7 going. In fact, I was told by C. P. that they
8 were not so concerned about testing the species
9 as they were of testing the reclamation expert.

10 I am happy to report that the
11 first year's results were very encouraging. With
12 the exception of the loss of some of the planted
13 shrubs due to record high temperatures last spring,
14 we have managed to get a good stand of grasses
15 and legumes growing on the slope.

16 Last fall we continued our operational
17 trials with the application of seed and fertilizer to
18 selected sites along the surface route. This is an
19 off center line drill hole that was put down.
20 This was just as the snow was melting in the spring
21 and this was a couple of weeks ago. You will
22 recognize this as the east portal, the reinforced
23 earth retaining wall - last fall, and this spring.
24 The Soper Creek. I hope you have had a chance to
25 see for yourselves the results of these trials.

26 This spring we were again on the
27 site cleaning up the damage caused when part of the
28 access road slid down the slope. We plan an
29 extensive reclamation program for later this
30

1 (Polster)

2 summer which, as I alluded to earlier, will include
3 trials of slope stabilization techniques along the
4 access road. We also plan to revegetate the slopes
5 along the vent shaft access road and the completed
6 portions of the east and west portals. This time we
7 will be testing the effectiveness of a late summer
8 planting period which, if successful will further
9 extend the times during which reclamation work
10 can be conducted.

11 I would like to comment briefly
12 on the revegetation of steep slopes and this
13 slope here is on the order of about 40-41 degrees
14 side cut slope. There was no special site
15 preparation work done prior to seeding to loosen
16 the surface or anything on this slope.

17 This slope, which most of you from
18 the Park will recognize as being just outside
19 the east gate, is one and a half to one and, in
20 fact, this shows a fairly good example of what
21 we anticipate the slope would look like with the
22 grasses near the track bed and, of course, we
23 are going to try to minimize the introduction
24 of dandelions. Trees and shrubs further up the
25 slope. I should point out that the trees and
26 shrubs in this case were all volunteers as far
27 as I know. There was no special attention paid
28 to planting trees or shrubs in this area.
29 Similarly there was no special attention paid to
30 top dressing materials or any of the assistance

(Polster)

we are proposing.

This slope is a face-on view of a rock fill slope just adjacent to Mountain Creek campground. In fact, right across from the Mountain Creek cuts I was just describing. It is an angle of proposed slope, 37 degrees. It is shot-rock from the slope above. No top dressing and the vegetation establishment is purely volunteer. 37 degrees is 1.3 to 1 approximately.

I realize I have covered a lot of ground in this presentation. I hope I have answered any further questions you might have, however, I would be pleased to answer any questions you might have or to elaborate on any aspect of the planned reclamation program. I would like to thank you for your kind attention.

Actually I should mention a few other things. I was handed last night a copy of the statement by the Panel's expert on reclamation in which he suggests reclamation standards be applied, and with a few exceptions, we agree to those standards, and I suspect this will be coming up after his discussion. Thank you.
--Brief adjournment.

THE CHAIRMAN: We will now recommence with Mr. Walker's presentation and then we will get into a discussion. I guess the one thing we need here is C. P. and I have not seen them back yet.

(Walker)

1
2 DR. DAVID WALKER (David Walker &
3 Associates Limited):

4 Thank you, Mr. Chairman, Panel
5 Members, C. P. and Ladies and Gentlemen:

6 This is the second technical
7 review that I have made of the C. P. reclamation
8 plan. The first was only of the consultant's
9 report and this review is primarily of the --
10 this second review includes the C. P. R. Red
11 document, which has some revisions to the technical
12 plan and more commitments made.

13 The review is presented in two
14 sections. One is the technical review and the
15 second section will be suggestions for
16 reclamation standards, which could be adopted by
17 Parks Canada and C. P. Rail in order to define
18 what an acceptable reclamation job is.

19 The objectives of the reclamation
20 plan presented by C.P.R. is excellent. A herbaceous
21 plant cover sufficient to control erosion has
22 been proposed. Recognition has been given to the
23 fact that the coarse textured soils distributed
24 locally along the route have a low moisture
25 holding capacity and top dressing with material
26 containing an acceptable proportion of fine
27 textured particles will help mitigate a potentially
28 droughty soil condition. Transplants of
29 indigenous trees and shrubs have been proposed in
30 order to re-establish a native plant community.

1 (Walker)

2 The plan indicates that a self-
3 sustaining plant cover will be developed and the
4 need for ongoing maintenance will be minimized.

5 The first technical review raised
6 a number of questions concerning the revegetation
7 plan. Some of these have been answered in the
8 most recent C. P. Rail submission by amendments or
9 by providing more information. Despite these changes,
10 however, serious doubts exist as to the ability
11 of the plan to achieve the stated objectives.
12 The following points outline the major questions.

13 First, Erosion Control:

14 The establishment of a cover of vegetation has
15 been proposed as the most effective and only
16 method of controlling sheet erosion. During the
17 period of plant establishment average erosion
18 control effectiveness of a rapidly establishing
19 perennial grass has been measured to be maximum
20 of 60 per cent. The period of plant establishment
21 may take as long as 12-16 weeks under the climatic
22 conditions in Rogers Pass. Even low rates of soil
23 erosion result in a seeding failure because
24 plants are uprooted.

25 The C. P. Rail revegetation plan
26 proposes that additional erosion control measures
27 may be applied if required. The additional measures
28 have been described in the vaguest of terms and no
29 comment can be made as to the effectiveness. For
30

(Walker)

1 example, a straw mulch has been mentioned without
2 reference to rate of application, source of material,
3 method of application, or the system of ensuring
4 adhesion to the slope. Soil binders have been
5 referred to without providing details on type,
6 application rate, and method of application.
7 Hydroseeders have a limited range of application
8 upslope.

9
10 The plan lacks criteria for identifying
11 an acceptable level of erosion form that is
12 unacceptable. Criteria are also lacking for the
13 choice of mitigation measures. This absence of
14 guidelines exposes the reclamation plan to
15 differences of opinion of the definition of
16 successful reclamation. In addition, an unsuccessful
17 initial attempt at reclamation may result in
18 rapidly escalating costs which may force abandonment
19 of the original objectives.

20 The second, is Self-sustaining
21 plant cover: In the past 10 years, considerable
22 effort and reclamation research has been devoted to
23 the achievement of a self-sustaining plant cover
24 on drastically disturbed lands. The establishment
25 of grasses and legumes or of transplants of native
26 shrubs and trees will not in itself provide a
27 self-sustaining permanent plant cover. The problem
28 is a soil nutritional one and repeated applications
29 of fertilizer will almost certainly be required.
30 B.C. Coal Ltd. of Sparwood has supported considerable

1 (Walker)

2 reclamation research to determine the length of
3 time required and the soil characteristics
4 necessary for a reclaimed area to be self-sustaining.
5 Definitive answers have not been found.

6 The reclamation maintenance program
7 referenced in the C. P. Rail submission and
8 outlined in the Norecol Reclamation Plan appears
9 overly optimistic in relying on nitrogen-fixing
10 legumes to reduce the need for repeated applications
11 of fertilizer. Full appreciation does not appear
12 to have been given to the fact that reclamation
13 of other similar disturbances in the mountain
14 regions of Western Canada have required lengthy
15 periods of intensive management.

16 The reclamation plan examined the
17 salvage of suitable surficial organic material for
18 use as top dressing, and by that I mean top soil.
19 C. P. Rail is strongly encouraged to commit to
20 this wherever possible. Replacement of surficial
21 soil material, containing even diluted amounts of
22 topsoil, will be of such benefit to revegetation
23 that Parks Canada should consider extra right-of-way
24 requirements for temporary storage of the material
25 if it is logistically required.

26 Sub-surface material has also been
27 considered for top dressing. Some sub-surface material
28 excavated to provide a firm foundation for the railway
29 bed may not be better for plant growth than the
30 material already on the surface. Material high in

1 (Walker)

2 silt and fine sand is highly erodible and its use as
3 a top dressing would increase the erosion potential
4 on steep slopes and the risk of sedimenting aquatic
5 habitats. Unless the excavated material is
6 substantially better for plant growth it should not
7 be top dressed as a means of disposal. Under
8 such circumstances, Parks Canada should consider
9 foregoing the policy of balancing earth quantities
10 in favour of disposal at an inconspicuous
11 location, and my rationale for that is if it is
12 going to erode off the slopes into the woods,
13 you might as well know exactly where it is going
14 and dispose of it in an acceptable place.

15 Establishment of vegetation:

16 The method of establishing a grass/legume cover
17 outlined in the Norecol Reclamation Plan is not
18 adequate to ensure a reasonable probability of
19 success. The potential adverse effects of
20 erosion during plant establishment has already
21 been mentioned. Other problems likely to occur
22 and not adequately addressed in the plan are
23 outlined.

24 Time of seeding:

25 Fall seeding is not expected to result in adequate
26 plant establishment because seed will be washed
27 downslope during spring run-off. The problem
28 cannot be mitigated by elevated seeding rates.
29 A suggested alternative is to restrict fall seeding
30

1 (Walker)

2 to areas with very coarse-textured soils. The
3 period of seeding could also be extended, in my
4 opinion, from early spring through to August 1.

5 Reliance on Remedial Seeding:

6 Despite commitments from C.P. Rail that
7 remedial seeding will be conducted to achieve the
8 minimum required cover, existing conditions strongly
9 suggest that subsequent seeding attempts will be
10 very difficult. Machine access to the slopes
11 may not be possible after construction has been
12 completed, and Mr. Polster has outlined that
13 scarification may be very necessary to prepare
14 a seed bed. Soil exposed to rain and run-off
15 results in severe breakdown of structure of the
16 soils due to the beating action of rain and the
17 assorting action of flowing water. The result
18 is the formation of a relatively impervious seal
19 on the soil surface which reduces the rate of
20 water infiltration into the soil, increases the volume
21 of overland flow, and exposes existing vegetation to
22 water stress. Surface sealing of the soil
23 eliminates the microsites which catch seed and
24 fertilizer pellets.

25 The C. P. Rail reclamation plan
26 places considerable reliance on a program of
27 repeated seeding attempts in order to achieve
28 adequate plant establishment. The application of
29 a mulch is suggested in order to reduce erosion,
30

1 (Walker)

2 maintain infiltration rates and provide additional
3 microsites for seeding establishment. For
4 example, a couple of indigenous materials which
5 should be rather cheap is wood chips from clearing
6 operations and slash, which I would define as
7 the smaller brush, small trees, 5 to 15 centimeters
8 in diameter, limbed and layed on the ground close
9 to the soil surface. The use of this material is
10 strongly over, for example, straw in order to
11 avoid introducing weed seeds into the Park.

12 Tree/Shrub Transplants, and this
13 is Phase 2 of the reclamation plan.

14 The reclamation plan calls for the
15 planting of woody species in spring within one
16 year of seeding operations. A cover of seeded
17 species is the only method of erosion control
18 and complete establishment of the herbaceous cover
19 may require as long as two full growing seasons.
20 Attempting the final reclamation step before the
21 method of erosion control has proven successful,
22 suggests a high risk of failure. While a commitment
23 to replanting has been made, the "desired stocking
24 rate" has not been defined.

25 I have a number of Miscellaneous
26 Comments to make. The C. P. Rail submission
27 contains information on revegetation not previously
28 mentioned in the Norecol Plan, and the following
29 are my comments:
30

1 (Walker)

2 Asphalt tackifier has been mentioned.
3 Asphalt is a light petroleum oil. It is proposed
4 to be hydroseeded on sections with exposed rock.
5 I feel spraying oil on rock faces is not an
6 appropriate method of mitigating visual impact. The
7 use of asphalt tackifiers has been banned in at
8 least four states in the U.S., because of
9 adverse environmental effects.

10 Use of Straw:

11 Straw mulch and straw bales have
12 been suggested for use in controlling sheet and
13 channel erosion. While straw can be an excellent
14 material for erosion control, the introduction of
15 weed seeds borne in the bales is almost impossible
16 to control. The use of straw within Glacier
17 Park is most inadvisable.

18 Reclamation Monitoring:

19 The monitoring program outlined
20 by C. P. Rail calls for the reclamation inspector
21 to be on site two weeks per month until field
22 personnel know the proper procedures. In the view
23 of the complexity of construction and coordination
24 of activities required, part-time supervision does
25 not appear adequate. Will the C. P. Rail construction
26 inspectors be on site only part-time and then only
27 until the construction contractor understands the
28 procedure?
29

(Walker)

1
2 I would like now to make some
3 suggestions for reclamation standards that could
4 be adopted by C. P. Rail and Parks Canada in the
5 form of an agreement. The adoption of reclamation
6 standards by the principles involved could provide
7 a clear understanding of expected results and ensure
8 a harmonious working relationship over the course
9 of the construction period and beyond.

10 Reclamation standards are commonplace
11 for construction projects under provincial
12 jurisdiction particularly in British Columbia
13 and Alberta. Reclamation procedures and expectations
14 are documented in several publications prepared by
15 the governments of British Columbia and Alberta.

16 Reclamation standards would be
17 of benefit to both C. P. Rail and Parks Canada.
18 Revegetation of drastically disturbed lands is a
19 relatively recent development and lacks a long
20 history of experience that could reduce differences
21 of professional opinion, and I guess it must be
22 clear by now that there are differences of professional
23 opinion here, and despite these I would like to add
24 that Mr. Polster and I are still talking. The
25 adoption of standards would allow C. P. to select their
26 method for achieving the agreed-upon results. A
27 reclamation bond is commonplace for most large
28 projects under provincial jurisdiction and is also
29 suggested in this case.
30

(Walker)

The following points outline reclamation standards which could be applied to various aspects relating to reclamation. Most of the parameters have been taken from the C. P. Rail submission or the Norecol Reclamation Plan.

D-1

(Walker)

The herbaceous cover of grass and legumes provides several functions: first, erosion control; visual impact mitigation; and the development of a self-sustaining soil profile. Therefore, two parameters are proposed. The first parameter: a plant density frequency. A minimum plant density of ten plants per square foot one year after initial seeding has been suggested by C.P. Rail as a criteria for remedial seeding.

My suggestion for a proposed standard for plant density is one plant per square foot, averaged within any area ten metres by ten metres, and occurring with a minimum frequency of 90 percent. Native invading plants should be included in this measure. The area of canopy cover of invading or transplanted woody stock should be excluded and areas of bedrock, blasted rock and shallow soil over bedrock should naturally be excluded.

A vegetative ground cover has been identified by C.P. Rail as the best and primary method of erosion control. As such, the vegetative ground cover criteria is of importance in providing adequate amount of erosion control. An intensive amount of research on the effects of associated mulch and vegetative canopy cover indicates a combined cover of over 90 percent can be 99 percent effective in controlling erosion. Erosion control drops quickly when canopy cover is below 70 percent. Therefore, the

D-2

1 (Walker)

2 proposed standard for vegetative canopy cover is
3 is an average of 80 percent canopy cover, including
4 detritus, this is dead plant material from a
5 previous year's growth, within any area ten metres
6 by ten metres.

7 The establishment of self-sustaining
8 vegetative. Vegetation must be capable of maintaining
9 adequate cover and density without the aid of applied
10 fertilizers well beyond the time when residual effects
11 have ceased. The proposed standard for measuring
12 self-sufficiency of vegetative cover is measurements
13 of plant density and canopy cover should be made
14 on areas not fertilized for a period of three years.

15 Stocking density of woody species.
16 The reclamation plan calls for transplanting densities
17 of 2400 to 4500 stems per acre. The proposed
18 stocking density of woody species including the
19 invading native species is an average of 1200 plants
20 or stems or living trees per acre growing at not
21 less than a 20 percent rate of adjacent similar
22 natives. This standard applies to all areas
23 originally transplanted.

24 The erosion control standard. Acceptable
25 levels of soil tolerance are dependent upon several
26 factors. Soil eroded off site into dense vegetation
27 during a three to five year construction period is
28 considered to be an unavoidable environmental risk.
29 Plants on the forest floor will be buried and low-
30

D3

1 (Walker)

2 lying areas may experience accumulations of sediment.
3 But the overall effect to the forest will be
4 minimal. Sedimentation of aquatic habitats is
5 best monitored by sampling. Water sampling is beyond
6 the scope of this review.

7 Soil loss tolerance for a reclaimed
8 area depends on balancing soil formation by weathering
9 and accumulations of organic matter with erosion
10 losses. Current soil conservation practice accepts
11 soil loss tolerances in the range of two to ten
12 tons per hectare per year, depending on the rate
13 of weathering and the climatic conditions.

14 The objective of a self-sustaining
15 vegetative cover requires that organic matter
16 accumulates as rapidly as possible. The proposed
17 standard for erosion control is not more than 100
18 tons per hectare per year. This provides a good
19 margin of air and for a cushion, I believe the
20 standard is low enough to protect Parks Canada
21 interests and yet high enough to allow some
22 variability on the reclaimed site.

23 Reclamation bonding. The posting of
24 a reclamation bond is proposed of sufficient size
25 that in the unlikely event of default, Parks Canada
26 would be sufficiently refunded to reclaim the
27 area themselves. Current costs of reclamation for
28 drastically disturbed lands ranges from approximately
29 \$13,000 to \$63,000 per hectare, depending on the
30

D4

1 (Walker)

2 quality required. These estimates include earth
3 moving, but the quality required for a national park
4 is high, therefore, the proposed reclamation bond
5 is \$20,000 per hectare. The area could be
6 partitioned and certification granted to various
7 sections when judged to be successfully reclaimed.
8 Assessments should be made in three year intervals
9 with a maximum ten year period after construction
10 with which to reach the specified standards.

11 That is my submission, Mr. Chairman.

12 THE CHAIRMAN: Thank you very much.
13 I guess we are going to have a number of questions
14 now. Perhaps it might be convenient if C.P.'s
15 consultants could come up and share the A table
16 with you. You can share it with C.P. or since
17 you are still talking to each other you can share
18 the same one over here.

19
20 I will start off a question and this
21 is concerning a presentation that was made yesterday.
22 I take it implicitly from your presentation that you
23 feel that given the 1.5 to 1 packed slopes in
24 many areas that C.P. is proposing and the
25 presentation by C.P. and the standards that you are
26 proposing, that you feel it will be possible,
27 albeit perhaps difficult to reclaim on those slopes
28 and meet the standards that you are proposing.

29 DR. WALKER: Yes.

30 THE CHAIRMAN: My question then is to

D5

1
2 C.P. as to the standards. I believe in your
3 presentation, Mr. Polster, you mentioned that you
4 were perhaps not in general agreement, that is
5 putting words in your mouth, but perhaps you could
6 tell us if you agree or which of these standards you
7 agree with or where you have some differences. That
8 would be very helpful.

9 MR. POLSTER: I will just go right
10 through them in the text as they occur in Mr.
11 Walker's text.

12 Plant density frequency, I suggested
13 a contract spec of ten plants per square foot one
14 year after. Dr. Walker is suggesting one plant
15 per square foot. It seems to me that what Dr.
16 Walker is aiming at is one big vigorous plant,
17 although I am sure that we are in accord there.

18 DR. WALKER: I was referring to
19 release of a reclamation bond, so that would be
20 several years down the line, whereas you are referring
21 to establishment one year after.

22 THE CHAIRMAN: The difference is in
23 here as between how you start off and how you end
24 up.

25 DR. WALKER: Exactly, but you can expect
26 a number of plants to die off.

27 DR. ROSS: That is something I wonder if
28 I could ask some more information about. It is
29 not clear to me what the survival rate is after
30

D6

1 the first year. Is it quite high or do I understand
2 that you are implying that the survival rate after
3 the first year will not be very high and
4 the difference of three years down the line and one
5 year down the line are likely to be quite different?

6 DR. WALKER: They are likely to be
7 very different and that is because large, vigorously
8 growing plants require a certain area, a certain
9 soil volume to exist and this seeding rate is much
10 higher than that density, so you anticipate a
11 considerable amount of die off.

12 It would appear from the C.P. plan
13 that they are aiming at a very high initial
14 establishment to act as an erosion control measure
15 and are therefore expecting a very high die off
16 rate, and this occurs by plants competing against
17 one another.

18 DR. ROSS: That is not a problem at
19 all. That is the normal evolution of this sort of
20 a ---

21 DR. WALKER: It is certainly very
22 normal but I would not say it is desirable because
23 what happens is the more vigorous or competitive
24 plants under the existing conditions which may at
25 that time be under fertilization conditions are the
26 ones that end up surviving and species that, for
27 instance, would be more competitive under lower
28 fertility conditions, for example the legumes, would
29 end up getting crowded out.
30

D7

1 DR. ROSS: So you are suggesting that
2 it may in fact be wiser to seed at a lower rate and
3 perhaps with some different species?

4 DR. WALKER: If you did that then
5 additional erosion control measures would be
6 necessary to make up the difference.

7 MR. POLSTER: If I might just interject
8 here. I have been involved in reclamation for
9 a fair number of years and have looked through the
10 literature at seeding rates especially on steep
11 slopes, and I will agree, the rates that I am
12 suggesting are high, you know, especially compared
13 to an agricultural situation, but they are not
14 outside of the limits which have been reported in
15 the literature or are suggested by various documents
16 from governments, various levels of government.

17 THE CHAIRMAN: Could I just ask a
18 question of time in this one. Presumably if there
19 was a bond there would be some pressure to get this
20 plan happily established in its square foot, but is
21 it reasonable to expect by the end of this
22 construction project that the standards will have
23 been met? In other words, could we see to this
24 reclamation as being achieved by that time or are
25 we thinking of this thing dragging on into the next
26 decade?

27 MR. POLSTER: I think that time is a
28 critical thing with reclamation, particularly the
29 establishment of the initial cover as that is our
30

D8

1 proposed means of controlling surface erosion.

2 As you are probably -- well, you may
3 be aware, all of the plants that I am proposing for
4 use in the initial cover are perennials, which
5 means that the first year of growth is relative
6 low key and the second year they start to really go
7 to town and produce seed and that sort of thing.
8 So that you get some establishment and some
9 control of erosion in the first year and the second
10 year it is covered. So that for the initial cover
11 you could expect to be able to assess your results,
12 say, after the second year after it had been
13 seeded -- well, two full growing seasons, let us
14 put it that way.

15 So if you seeded in the late fall, with
16 the spring emergence, then you would go another
17 full growing season after that.

18 With the shrubs, you would want to
19 probably wait three or four years before you had
20 determined that they were permanently established
21 and that things were going as planned.

22 THE CHAIRMAN: I believe Mr. Fox is
23 going to be chipping away at his tunnel for some
24 time after the surfaceway has been done, a number
25 of years, so presumably by close to the end of the
26 construction project you would have an idea whether
27 this thing was going to be established and meet
28 the standards?
29

30 MR. POLSTER: Yes, I think for part of

D9

1 it you would, yes, but of course the surface route
2 is going to be going as well and you are also going
3 to be using part of the tunnel fill on that section
4 between the short and the long tunnel.

5 So I would suggest that we look at
6 standards a couple of years after the initial erosion
7 controlling revegetation effort and maybe five years
8 after the planting of woody species.

9 THE CHAIRMAN: If you want to go on
10 through the standards, then, please.

11 DR. WALKER: Could I add something to
12 that, Mr. Chairman?

13 You are missing one of the parameters
14 and that is the creation of a self-sustaining
15 plant cover, and in order to do that on a drastically
16 disturbed site, you must replace the organic matter
17 which is the pool of nutrients and in this case
18 where topsoil is not or cannot be replaced, you are
19 in essence growing your own topsoil by fertilizing
20 grasses and each year that the roots and the stems
21 die off and decompose, you are adding more organic
22 matter.
23

24 This process is expected to take a number
25 of years for this to build up and then there will
26 be a period of no fertilization before you can
27 determine whether it is in fact self-sustaining.

28 In my opinion we are looking at perhaps
29 a five year period of good maintenance and then
30 another three years at least of waiting to see how

D10

1 it is going to look. It could very well be a ten
2 year period before the bond would be released.

3 THE CHAIRMAN: Do you want to continue
4 through your standards?

5 MR. POLSTER: Okay. I agree that an
6 80 percent cover is a reasonable standard to expect
7 for control of erosion and with the exception of
8 rock slopes and those parameters you mentioned
9 before, I agree with that.

10 I think that it is true that we cannot
11 propose to access the success of the revegetation
12 effort while we are continuing to supply nutrients
13 and I might point out that as opposed to the approach
14 that is taken by B.C. Coal, one of the operators in
15 southeast B.C. who probably has the largest area
16 under reclamation right now in which repeated
17 applications of fertilizer of some 200 pounds per
18 acre are used every year, we are going to be taking
19 the approach that Fording Coal has taken and the
20 Cominco research group has developed.

21 Getting legumes established is an
22 important part of the reclamation program so that
23 we do not have to go into that heavy fertilizer
24 program. I think that as Dr. Walker has pointed out,
25 with an artificially maintained fertilizer program,
26 what happens is you get survival of those plants
27 that are best adapted to that program and not
28 necessarily the plants that are best adapted to the
29 environment.
30

D11

1 Now, I agree with Dr. Walker that
2 it is critical that we get the organic matter build-
3 up in the soil. You know, I differ in the approach.

4 Anyways, I think that measuring plant
5 densities after three years of non-fertilization
6 is reasonable.

7 I think the average number of stems
8 per acre for woody species is reasonable, although
9 on the low end of the range, suggested in the
10 literature for erosion rates, I think that the rate
11 of erosion is one which we can attain.

12 I think I will let Mr. Fox address the
13 bonding issue.

14 MR. FOX: Do you want me to address it?

15 THE CHAIRMAN: Sure.

16 MR. FOX: Well, I am not sure that
17 Dr. Walker is aware of rules and regulations and the
18 laws that govern railways. Have you ever read the
19 Railway Act, Dr. Walker?

20 DR. WALKER: No, sir, I have not.

21 MR. FOX: Well, in the Railway Act,
22 they can just about tell the railway exactly what
23 they can do, when they are going to do it, and how
24 they are going to do it and make sure it is done.
25 If you do not do it, you can end up in jail. It
26 seems to me that is a lot better than a bond,
27 particularly when you are talking to a multi-billion
28 dollars corporation.

29 I would suggest to you, sir, bonding is
30

D12

1 quite a thing to do for small mining operators who
2 make a hell of a mess and then go bankrupt. I
3 agree with that 100 percent, but when you are dealing
4 with the railway with the laws that govern us I
5 disagree wholeheartedly.

6 DR. WALKER: Sir, I do not believe that
7 the Alaska Highway Gas Pipeline or Syncrude
8 could be considered a small project.

9 MR. FOX: But they do not have the
10 Railway Act governing them.

11 THE CHAIRMAN: Maybe I could ask
12 Mr. Tikkanen whether the Railway Act would apply
13 in the degree of detail concerning something like
14 re-establishment of vegetation cover.

15 MR. TIKKANEN: That is a very good
16 question. We have not -- I cannot think of an
17 instance where it has been an issue before the
18 Commission. There are references in the Railway
19 Act which deal more generally with terms like
20 restoring the draining, the pipelines, this kind
21 of thing to where they were before the railway began
22 its work, but I think it is probably a lawyer's
23 question at this stage.

24 However, I think on the basis of
25 practical experience that I am aware of, the
26 railways I think have shown the intent of
27 restoration. I do not think there has been glaring
28 examples of where they have not recognized that
29 sort of responsibility in the past. However, as I
30

D13

1 say, it perhaps is a question for the lawyers of
2 the Commission and the lawyers of the railway.

3 THE CHAIRMAN: Is there any possibility
4 that you could get back to us with advice after you
5 checked with your lawyers on that particular issue?
6 If you have anything further to add I would
7 appreciate an answer.

8 MR. TIKKANEN: I will check that out
9 and let you know, yes, certainly.

10 THE CHAIRMAN: Thank you very much.

11 MR. FOX: Ken, before you go away, I
12 think if you look at the Railway Act, there is one
13 clause in there that covers everything, including the
14 kitchen sink.

15 MR. TIKKANEN: 104?

16 MR. FOX: Yes. Well, they can make
17 you do anything under that clause.

18 MR. TIKKANEN: It covers everything but
19 in about three or four lines.

20 MR. FOX: That is right, it does not
21 leave any loopholes either.

22 DR. ROSS: Mr. Fox, is that the
23 section you read to us at the last hearing?

24 MR. FOX: I believe it is, yes.

25 MR. TIKKANEN: Well, I think my
26 reference to the railway's intent, good intent is
27 probably demonstrated by Mr. Fox's approach here
28 but he recognizes that in that particular section of
29 the Railway Act there are serious responsibilities
30

D14

1 on the part of the railways to conduct
2 restoration.

3 THE CHAIRMAN: What would you do if
4 there is a disagreement as to whether something is
5 adequate restoration. Say, for example, Lake Louise,
6 if Parks are not happy and C.P. are happy, how would
7 you resolve that particular -- if there was a
8 dispute. It is a hypothetical question.

9 MR. TIKKANEN: Well, the mechanism in
10 the Commission for taking positions on these things
11 is to issue orders, and the Railway Transport
12 Committee would issue an order calling for whatever
13 the works might be.

14 If the railway is not pleased with that
15 order or feels that it is beyond the jurisdiction
16 of the Commission, its mechanism is to take the
17 disagreement to the Review Committee of the Commission.
18 The Review Committee of the Commission renders its
19 decision. If the railway still does not like that
20 decision, it can go to the Federal Court.

21 THE CHAIRMAN: Presumably if we have
22 got agreement on what the standards are. We can
23 hardly go out and count plants and see they had been
24 met.

25 DR. ROSS: But could I get back to
26 the beginning of that. You said that the Commission
27 would issue an order.

28 MR. TIKKANEN: Yes.

29 DR. ROSS: Now, how would the
30

D15

1 Commission decide whether or not that order is the
2 appropriate solution. That is, if in this sort of
3 a case Parks and C.P. were of a difference of
4 opinion regarding the satisfactory reclamation,
5 would CTC automatically issue that order to the
6 railway and then have it appealed, or would CTC
7 make a decision as to whether or not that order
8 is appropriate?

9 MR. TIKKANEN: I think in this particular
10 project, the order has already been issued. That
11 was the decision of last March 9th or a year ago
12 March 9th.

13 The decision basically states, I think,
14 although it does not set out environmental standards
15 or work standards, I think the order and the decision
16 which is part of the order is quite specific in
17 the sense that it requests that the railway work to
18 a standard which is recognized by Parks Canada.
19
20
21
22
23
24
25
26
27
28
29
30

1
2 THE CHAIRMAN: Thank you very much ,
3 Mr. Tikkanen. It is very useful to have you
4 here to answer those questions.

5 MR. FOX: Mr. Chairman, it is
6 Section 103 and 104 of the Railway Act and it is
7 contained in the order that was released concerning
8 this particular Project.

9 THE CHAIRMAN: Thank you. The
10 questions that follow along that is that the
11 performance and the level of quality that is
12 expected, if there is an agreement, basic agreement,
13 on what is expected for satisfactory work, where
14 does the responsibility lie from your point of
15 view, Mr. Fox? Do you use contract help for the
16 work of reclamation with your consultants advising
17 as to whether the work is being properly done?

18 MR. FOX: That is correct.

19 THE CHAIRMAN: So that if it does
20 not meet standards and if you have got these sort
21 of standards written into the contract, you just
22 go to the contractor and say you did not perform,
23 or is it something where you have to pay them to
24 do the work, and if they are not successful you
25 have to pay them to come again?

26 MR. FOX: Well, you can do it
27 two ways. You can take your approach which is
28 one approach, and the other approach is as your
29 are looking at something that is going to last over
30 a number of years, from what I can understand from

1 these two experts here, would be in that vein.
2 In all possibility I would ask for a performance
3 bond that would extend over that period of time from the
4 contractor and then you would get them where you want
5 them.

6 THE CHAIRMAN: It would transfer
7 the responsibility to the contractor.

8 MR. FOX: Well, he is the guy that
9 is going to do the work and he is supposed to have
10 that necessary expertise or he should not be in the
11 game. So if he has got that expertise, he can get
12 a bond.

13 DR. ROSS: Mr. Fox, was Mr.
14 Pölster speaking for C. P. Rail when he concurred
15 with those standards?

16 MR. FOX: He certainly was,
17 Doctor Ross.

18 DR. ROSS: Doctor Walker, these
19 standards, are they sufficiently objective that
20 anyone making those measurements would be expected
21 to get the same sort of results or do they require
22 some sort of interpretation of what is in the field?
23 What I am thinking of is a matter of who should
24 make the decision as to whether or not the standards
25 have been met. In some cases, they would simply
26 be a matter of putting a meter on top of plants
27 and seeing if that is the red line, and if that is
28 the case, then anyone could make the assessment,
29 but in other cases, if it requires some interpretation

1 of what is there perhaps one should use an
2 independent assessor to make those determinations.

3 DR. WALKER: I would recommend
4 an independent assessor. Much of the error that
5 could be introduced with these measurements comes
6 from the choice of location, and so some independent
7 method of statistically sampling the area would
8 be warranted. Certainly the actual measurement
9 methods themselves are well documented methods
10 in practice in plant ecology.

11 MR. TENCH: Doctor Walker, I am
12 still having trouble on this erosion figuring
13 here. It seems that soil loss tolerance of 2 to 10
14 tons per ~~hectare~~ per year is the going rate and yet
15 we can leep right to a 100. I know you discussed
16 this before but I could not see the relationship
17 of those two figures.

18 DR. WALKER: Well, naturally
19 it would be to C. P.'s advantage to get their
20 soil loss tolerance to keep their soil losses
21 below the acceptable soil loss tolerance of for
22 example of ten tons per hectare. So I am not
23 particularly concerned about that because if they
24 are creating self-sustaining plant cover, they will
25 have to meet that. So I added a factor of 10
26 to give them some leeway but also to set a level
27 that would give Parks Canada some protection for
28 continued erosion off the right-of-way onto their
29 property.
30

1 I am also anticipating that C. P.
2 will have a much higher soil loss tolerance because
3 during those early periods they will be attempting
4 to accumulate organic matter and will be fertilizing
5 and will be very likely to be accumulating soil
6 at a much higher rate than the normal weathering
7 pattern.

8 THE CHAIRMAN: If I could follow
9 up on that -- presumably your line of thinking
10 then would be to have an independent expert again
11 measuring with a rill meter or whatever what the
12 soil loss is, but then my second part of my
13 question is if you find yourself with a standard,
14 what do you do, and maybe I could ask you and
15 then ask C. P. to respond to that.

16 The first one is presumably you
17 want an independent expert to measure the soil
18 loss?

19 DR. WALKER: Yes, although I am
20 sure C. P. would also want and have indicated they
21 will be doing their measurements and will have
22 a fairly good idea of what is going on, but I
23 would suspect if the issue is over the release of
24 a reclamation bond that an independent assessment
25 would be necessary.

26 THE CHAIRMAN: I think I am more
27 concerned about the beginning where problems
28 might occur, getting the plants established,
29 and if somebody felt that there was a lot of
30

1 erosion taking place -- how do you deal with that
2 particular problem, and for the worse case where
3 you lose a whole portion of the bank, and I have
4 seen many examples of these along the highway?

5 DR. WALKER: I realize that by
6 simply letting C. P. conduct their reclamation
7 program in their own manner and then setting
8 a reclamation standard that leaves a hole in that
9 case -- it leaves a hole like there is no control
10 during that construction period or the early
11 periods as to the rate of erosion, et cetera, but
12 as I stated if there are slumps or periods of
13 serious erosion where sediments and soil material
14 is transported into the trees, I do not anticipate
15 any long term adverse environmental effects.

16 If that soil is deposited into
17 a water course, then I would anticipate the water
18 quality standards that Doctor Adam mentioned yesterday
19 would be in effect and that reclamation work would
20 be prompted on those standards.

21 THE CHAIRMAN: How difficult is it
22 going to be to get some material back on that
23 slope again and maybe this is --

24 DR. WALKER: It is going to be
25 exceedingly difficult and I would assume that if
26 these standards are agreed to that C. P. would
27 be making every effort to keep the slope, this
28 soil on the slope and get a good catch the first
29 time.
30

1
2 THE CHAIRMAN: I do not know whether
3 you want to respond to that C. P., but one additional
4 point I would like to know is that if you do get
5 an event where you lose part of the bank, are
6 you going to end up in an argument between the
7 contractors - one that says it is pretty hard for
8 me to reclaim this thing when it has disappeared on
9 me down the hill.

10 MR. POLSTER: I just should point
11 out that there are two different things we
12 are talking about here. One is controlled surface
13 erosion and the other is the control of geotechnical
14 stability, and I suggest that if you are talking
15 about banks sliding away you talk to the geotechnical
16 experts.

17 With control of surface erosion
18 what I would suggest for the standard is that the
19 100 tons per hectare per year be adopted as a
20 standard averaged over two yeras, because -- so
21 that that standard would be applicable to any one
22 year, but that obviously if you had a 125 tons the
23 first year and you were down to 12.5 the second,
24 then because of the time required to get vegetation
25 established, that is what I would suggest. That
26 it be averaged over a two-year period to allow
27 for the establishment of vegetation. Now obviously
28 we are going to be concerned about -- you know, if
29 we find that the rates are high, we are going to
30 be concerned about the downstream effects and that

1 sort of thing. We are also going to be concerned
2 about how well we are going to do the next year.

3 So we will be going in with measures to control
4 that, and we will be testing some of those measures
5 this summer - application of soil binding sprays
6 that sort of thing. So that is what I would
7 suggest for the standard there.
8

9 MR. TENCH: Doctor Walker, on
10 page 6 of your Report, you mention that there are
11 several other examples of reclamation in similar
12 mountaineous areas. I presume of this magnitude
13 and type. Would you like to give us a short talk
14 on some of them and the rate of success they have
15 achieved and the length of time that they have
16 taken to revegetate and reclaim.

17 DR. WALKER: Well, the area that
18 is most similar and that I know best is the Lake
19 Louise area, which I have acted as a consultant
20 for four years and as a research graduate
21 student for three years previous to that, and I
22 found that the dependency on fertilizer has been
23 rather site specific, and I suspect dependent
24 largely on species composition that I have managed
25 to get established; a number of other factors
26 like moisture availability, et cetera, but it is
27 generally found that three years is necessary to
28 maintain to the initial cover and, of course,
29 now the time constraint is coming in and I cannot
30 tell you. After that there are some sites which

1 appear to be requiring fertilizer every two years,
2 every three years, and others that are requiring
3 fertilizer twice a year. As I say the research
4 has not been going on long enough to know exactly
5 what the length required is and what kind of soil
6 parameters could be measured easily to determine
7 whether it is self-sustaining.
8

9 The B. C. Coal experience has
10 shown that while very large pools of organic
11 matter can be built up, is it necessarily sufficient?
12 It depends also then on the breakdown of this
13 organic matter, and the plants that you use to
14 get them build up that organic matter may not
15 be the most ideal plants for growing under those
16 conditions. So you are then faced with a species
17 change requirement.

18 MR. POLSTER: I would like just to
19 comment on a few things. First of all, the Lake
20 Louise situation is not comparable to the Rogers
21 Pass situation. The Lake Louise situation is
22 probably more comparable to the B. C. Coal situation
23 where you are dealing with elevations on that order
24 of magnitude and climatic conditions on the top
25 of Harmer Ridge on that order of magnitude.

26 The other thing is that in talking
27 about the B. C. Coal situation, I think it is
28 important to point out the extent of the reclaimed
29 area and the effort to which B. C. Coal has gone to
30 in reclaiming their areas in terms of nutrient cycling.

1 I might add that B. C. Coal is
2 the largest operator in B.C., coal mining operator,
3 and they have some 6,000 hectares under disturbance
4 of which they probably have about 2,500 under reclamation,
5 and what happens when you get those large areas dis-
6 turbed and under reclamation that you have no chance
7 of getting natural soil organisms from adjacent sites
8 onto the site, and it has been found that the
9 soil micro-organisms, nematodes and bacteria and
10 all sorts of other things, play a large role
11 in the nutrient cycling. On the other hand, if
12 you look at exploration disturbances, which are
13 more on the order of what we are talking about
14 where trenches have been dug and that sort of thing,
15 you find that the natural cycling of nutrients re-
16 establishes quite quickly and there is very few
17 exploration disturbances which are re-fertilized
18 every year on the B. C. Coal property. It is
19 their large areas that require repeat applications.

20
21 DR. WALKER: I would have to disagree
22 with the statement about the large area and, therefore,
23 the invasion of the micro-organisms is a factor.
24 Studies by Doctor Parkinson of the University of
25 Calgary for example have found that invasion of
26 bacteria is very, very rapid. I think the situation
27 is similar by important factors, such as the
28 steepness of slope, the alkalinity of the soil for
29 example, the aspect, the lack of organic matter for
30 example, but let us not get into this kind of a

30

discussion. It does not seem to be productive. I know experts can talk weeks on this very topic about nutritional exchange. I believe that you will have to watch the area very carefully to achieve a self-sustaining cover and you should be ready to keep the maintenance up for quite some time.

MR. FOX: I wonder if I could just ask a question. How exact is this science? We have got two professionals here who are talking to us and they sure as hell cannot agree. How exact is this science?

DR. WALKER: It is as exact as engineering I imagine.

MR. FOX: I doubt it very much. You cannot sure as hell put a mathematical equation to it. Having said that, you know I am just an old farm boy -- I was brought up on a farm, and it seems to me if you put your mind to it, you can do a lot of things, and one thing you can sure put your mind to is to grow something, and that is really what it boils down to in the final analysis. We have been farming in this world for a long, long time and we have been feeding everybody. There is not too much difference in that.

DR. WALKER: I have to agree with you, sir. If you put your mind to it, I do believe you can grow things.

MR. FOX: Well, that is what I am

1 going to do is put my mind to it. I can assure
2 you and I have been saying that now for two years.

3 THE CHAIRMAN: I have got one
4 question concerning the use of mulch. I believe
5 you mentioned chopping up trees and using the
6 particles from that. I am wondering how that
7 relates to the problems we heard about the bark
8 beetle. We heard that good sanitation was being
9 proposed in order to avoid these problems. This
10 came up in Golden, I believe. Does anybody know
11 whether this mulch, chopped up pieces of trees,
12 would be a home for these bark beetles and,
13 therefore, risk introducing an infestation.

14 MR. POLSTER: On that wood chip
15 deal that was tested at B. C. Coal and has been
16 used what they found that was they needed to apply
17 such large rates of nitrogen fertilizer to assist
18 the break down of the cellulose in the wood that
19 it pretty well was a lost situation. I do not
20 believe they are doing very much wood chip mulching
21 anymore. They did it at one point.

22 DR. WALKER: It depends greatly
23 on the rate of application as I am sure you are aware.

24 MR. FOX: I would like to ask a
25 more practical question -- what happens in case
26 of a fire on good dry periods of time?

27 DR. WALKER: Again I am not
28 suggesting that such high rates are required to
29 achieve the desired results.
30

1
2 MR. FOX: Well, if you spread
3 wood chips around I can assure you that there
4 are going to be lumps of them here and there and if
5 you get a fire started up a side hill like that
6 on a windy day when it is good and dry, it is
7 goodbye forests and National Parks.

8 DR. WALKER: A proper method
9 of application includes working this into the
10 ground somehow or fixing it in. Again, I must
11 say that low rates would not be a fire hazard
12 and particularly in the Rogers Pass area. This
13 method has been used in Alberta in forestry
14 and their conditions are much dryer than the
15 Rogers Pass.

16 THE CHAIRMAN: You do not know
17 whether it would be a home for the beetles though?

18 DR. WALKER: I believe the beetle
19 problem is at present theoretical but erosion
20 is not at the present. So my choice would be to
21 use that.

22 THE CHAIRMAN: I guess we probably
23 haveto talk to our forester about this-if we ever
24 got into that degree of detail, but it seems to be
25 a point that might be worth checking out given
26 that we were given this warning of this beetle
27 that is just up the valley.

28 MR. POLSTER: If I might just
29 comment, I think the application of mulch is
30 designed to control erosion and that really if

1 we fall back on our erosion standard that it
2 does not really matter whether we use Deci 162
3 or we use an application of wood chips or we use
4 cellulose fibre mulch and a hydroseeder, or
5 whatever method we use.

6
7 THE. CHAIRMAN: I would not have
8 been overly concerned except I heard something
9 about a problem yesterday and I had a professional
10 giving me some advice and I think it is always,
11 when I hear that sort of thing, worth checking out
12 before you proceed ahead and do so -- get some
13 more advice, and it seems only sensible.

14 MR. TENCH: There has been
15 some discussion about spraying rock faces with
16 asphaltic compounds. Could we have a discussion
17 between the two experts on that to see if we can
18 arrive at some decision on this at the Panel-
19 end of the proceedings. Apart from the fact that
20 spraying asphalt of rock faces is a good fire
21 hazard as well, I do not know what the wood chips
22 would be.

23 DR. ROSS: Could I in particular
24 ask Doctor Walker to elaborate on what the adverse
25 effects of that spray are?

26 DR. WALKER: Well, for one thing
27 when they studied its effect on plant emergence
28 they found that the asphalt decreases plant
29 establishment. It is true asphalt can at certain
30 concentrations be effective in controlling erosion

1 and if erosion is the limiting factor for plant
2 establishment then you will see improvement. Where
3 it is not, then you will see a decrease in plant
4 establishment. The stain, I believe, is a visual
5 stain that will remain for quite some time. It is
6 a problem or has been a problem in some cases with
7 dogs, kids, people, getting covered in the material.

8 MR.POLSTER: Mr. Chairman, the
9 suggestion for use of asphalt emulsion on the rock
10 cuts was solely to reduce the glaring visual
11 impact of light coloured rock cuts during the first
12 few years of the operation. It was not intended
13 as a long-term thing, but just to minimize those
14 rock cuts as we are getting the rest of the
15 reclamation program going.

16 As Parks suggested that we minimize
17 the visual impact that was one suggestion that
18 we had for minimizing it. I am sure C. P. would
19 be happy not to apply that asphalt tackifier if it
20 was deemed inappropriate for the situation. It just
21 costs money.

22 DR. WALKER: The money would be
23 far better spent on long-term reclamation.

24 THE CHAIRMAN: Parks do you have
25 any comment on the application of that material?

26 DOCTOR LEESON: Well, we would
27 have to see some of it. We do not really know
28 what you are talking about. I saw it up at
29 Abraham Lake five or six years ago but I do not know
30

1 if -- along the David Thompson -- is that the kind
2 of thing you are talking about?

3 DOCTOR WALKER: That is what I am
4 talking about and they have tried to revegetate the
5 David Thompson three years now using asphalt and it
6 has been unsuccessful every time.

7 DR. LEESON: If that is exactly
8 what is being talked about, it is a pretty unpleasant
9 looking material.

10 THE CHAIRMAN: Any further
11 questions?

12 MR. POLSTER: I would just comment
13 that we are not using it as any part of the
14 revegetation program. It is not a point in terms
15 of revegetation. It is solely for visual impact
16 amelioration where the landscape architect has
17 drawn on his experience and found that it has been
18 successful.

19 MR. MacGREGOR: Except that the
20 negative visual effects that you perceive are for
21 close-up, where you have to remember that we will
22 be looking at this from about half a mile away. It
23 is purely to keep down the glare of the light beige
24 colour as it contrasts against the deep green of
25 the coniferous trees, and, of course, we will not
26 be growing vegetation on those rock faces. So we
27 know that it will not have an effect on the vegetation.

28 THE CHAIRMAN: Okay, that is what
29 I would like to clarify: you are only intending
30

1 to put it on the rock faces?

2 MR. MacGREGOR: That is right.

3 THE CHAIRMAN: So your markings
4 on the visual impact analysis have given me the
5 impression that it was going to be put everywhere,
6 but what you are saying is only on the rock faces?

7 MR. POLSTER: Only on the rock
8 faces and only because we got into that situation
9 at the entrance to the Park where we were squeezed
10 in between the river and the existing line, where,
11 of course, we were in rock.

12 THE CHAIRMAN: So you would be
13 relying on the establishment of your vegetation
14 to reduce that glare of the soil material.

15 MR. POLSTER: That is right. As
16 we mentioned, it is a one-shot effort and once the
17 vegetation has re-established, we do not feel it
18 will be necessary.

19 THE CHAIRMAN: Thank you. Are
20 there any other questions, Panel?

21 DR. ROSS: Doctor Walker, did
22 I understand from your presentation that you
23 were suggesting an increased use of topping materials
24 or an increased use of top soils specifically?

25 DR. WALKER: An increased use of
26 top soil specifically and a decrease based on, and
27 I understand that there will be inspection of the
28 top dressing material that is excavated, a decrease
29 in the top dressing of that material, if it is not
30

1 better than what is already there. It seems that
2 top dressing has become a means of disposal.

3 DR. ROSS: The next point is
4 the question of time of seeding. I understand,
5 with perhaps some flexibility too, you suggested
6 no seeding after August 1st. Would that, in effect,
7 shorten the construction period? That is, do I
8 understand you or perhaps I am putting together
9 some of the suggestions that you and Mr. MacDonald
10 mentioned yesterday, would combine to shorten the
11 construction period in the sense that slopes needing
12 revegetation for erosion control would then be
13 precluded from coming into being later in the
14 season, effectively after August 1st. Is that a
15 reasonable interpretation?
16

17 DR. WALKER: No, it would not.
18 There would not be those constraints. I guess by
19 way of explanation, I should provide a little more
20 information. I work with the universal soil loss
21 equation or a modification of it, and I did some
22 calculations with data similar or we will call it
23 similar to the Rogers Pass area, because not enough
24 information was available, and what I found was
25 that the rainfall factor for that area for the
26 summertime is very low. I was very surprised
27 my first calculation was 4.6. So I re-did it in
28 another method and it came out to 2.7.

29 For example, rainfall factors
30 in the mid-western States may be 100, and in the

1 Mississippi they may be as high as 500. I guess
2 what that is saying is that it has a numerical
3 description of it -- it just drizzles a lot in Rogers
4 Pass. The maximum 24-hour rain is quite low.
5 So what that means is that erosion during summer
6 construction period is not expected to be high
7 based on the rainfall factor, and, of course, during
8 winter when there is no running water, it is also
9 very low. It is during the spring run-off period
10 that it is very, very high and as much as 90 per
11 cent of the erosion during the year will occur
12 during the spring run-off period.

13 In fact, when I calculated a run-off
14 or a rainfall factor based on the snow pack and the
15 melt of the run-off, it was quite high, and a factor
16 of about 60. So you are not going to stop construction
17 in August because you cannot revegetate it, because
18 it does not make any difference. It still has to
19 go through the run-off period. The August 1st
20 cut-off was simply to aid plant establishment and
21 that the seedlings that get started after August 1st
22 simply are not large enough generally speaking to
23 go through the winter period and still survive at
24 a high percentage?

25 MR. POLSTER: Would you like a
26 comment from this side of the Panel?

27 DR. ROSS: Oh, yes, surely.

28 MR. POLSTER: I showed in my
29 presentation the effects of fall seeding, fall applicat
30 on

1 of seed on very steep slopes, and I do not know
2 that -- well, I probably did not mention it, but
3 one of the things that we were testing there was
4 the fall seeding. The idea in that is not that
5 you get germination that year but get germination
6 the following spring. One of the things we learned
7 from that obviously -- well, that it is an effective
8 means of getting grass cover established as early
9 as possible ---
10

11 DR. ROSS: Excuse me, I missed
12 a negative in there. Did you say it is effective
13 or it is ineffective?

14 MR. POLSTER: It is effective at
15 getting a grass cover. However, because of the
16 biology of legume seed, and you know we could go
17 into that for hours, the legumes do not seem to
18 over-winter very well. I thought they probably
19 would because of the heavy snow cover, but this is
20 a common experience in reclamation. So we may
21 find that with fall, late fall seeding, and that
22 was seeded in October just before the first snowfall,
23 well, during the first snowfall, that with that
24 late fall seeding we can get grass established and
25 we have to come in and redo the legumes.

26 DR. WALKER: Are you saying that
27 you did not get any legume establishment from the
28 last fall seeding?

29 MR. POLSTER: There was very
30 little.

1
2 DR. WALKER: I thought those
3 photographs argued for my point, so maybe I should
4 elaborate a bit. In addition to the rainfall
5 factor, there is a soil erosivity factor and a slope
6 steepness factor which we have certainly talked
7 a lot about, but there is also a length of slope
8 factor in there which is almost as important as
9 the steepest of the slope and the pictures that
10 Dave showed certainly indicated a good stand, but
11 I should point out that they were, in most cases,
12 indicated short slopes. The east portal had a
13 concrete wall just above it, so that there is not
14 a large length of slope in that case, and even the
15 cut bank or even the fill slope that was photographed,
16 you were looking at the top of the slope and the
17 length of the slope is not particularly long in
18 that case.

19 When you add in slope lengths of
20 240 feet at angles of 60 per cent, the probability
21 of erosion becomes very, very high, and my first
22 suggestion for mitigation of this problem is to
23 partition the slope by breaking it up into short
24 segments, putting erosion berms across slope, which
25 drain into vertical waterways, and try and break up
26 the abnormal and very long slopes to try and mitigate
27 that action.

28 MR. POLSTER: I might point out
29 that we do not expect to have 260 foot slopes bare
30 at any one time. Because the construction is

1 going to go over a couple of years, and we will
2 be conducting reclamation as a sequential thing each
3 year, we do not expect to have the entire slope for
4 any particular cut bare at any one time, on long
5 cuts and fills, you know, large volumes of material
6 are being moved.

7 THE CHAIRMAN: Maybe we can move
8 along at this point to any other questions in
9 different areas that people might have.

10 DR. ROSS: I am reluctant -- I have
11 one more question for Doctor Walker, and I did not
12 want Mr. Polster to feel unwanted. I have several
13 questions for him later on.

14 Finally for Doctor Walker, did I
15 understand you to suggest that you would recommend
16 delaying the introduction of woody species for two
17 or three years until the herbaceous cover was fully
18 established?

19 DR. WALKER: Yes, I would, because --
20 again though that is a suggestion that it is more
21 benefit to C.P. Rail than it is perhaps to Parks
22 Canada, if the reclamation standards are adopted,
23 and that is because C. P. Rail may be in the position
24 of having to go back onto a slope to reseed it and
25 thereby destroying perhaps a considerable number of
26 well established wooden plants just because some
27 areas have not been revegetated.

28

29

30

F-1

1 MR. POLSTER: I might just comment on
2 the woody plants. In order to avoid competition
3 which was suggested in the first review of the
4 reclamation plan, the excess competition by trying
5 to establish woody plants in a dense grass legume
6 stand is well documented. We were trying to
7 avoid that problem by establishing almost immediately
8 so that as the grass legume stem grows up so does
9 the woody plant and you minimize your losses from
10 rodents and stuff.

11 DR. WALKER: I think you will find it
12 also well documented that even that is not a very
13 good method of doing it.

14 THE CHAIRMAN: I believe we are going
15 to switch across to a question on visual impact
16 assessment now.

17 DR. ROSS: First of all, I guess,
18 Mr. MacGregor, I was looking at your work, both your
19 presentation today and the document. It seemed
20 to me that there were a great many very valuable
21 contributions from the visual impact assessment
22 work, but I was puzzled by your treating either
23 superficially or not at all three issues which I
24 thought would have had a significant impact on the
25 aesthetics of the area, one of which is the width
26 of the right-of-way, the second of which is the
27 bridges, and the third of which I guess is now no
28 longer relevant, that was the electric power
29 transmission line.
30

F-2

1 It seems to me that the width of
2 clearing especially seemed not to be treated as
3 thoroughly as I would have thought, especially in
4 the one area where there is the siding. It seems
5 to me that the very presence of that siding which
6 is both in a very visual area and on top of some
7 landslide areas was a peculiar place to put that
8 siding.

9 I guess to Mr. Fox, is there any
10 alternative siting for that siding?

11 MR. FOX: None whatsoever. We looked
12 that land over and over and over again and that is
13 the only logical place to put that siding, not
14 only from the point of view of construction but from
15 the point of view of operations.

16 DR. ROSS: What about west of Connaught
17 Creek, between there and the east portal?

18 MR. FOX: You have not got enough room.
19 That siding is almost two miles long. You have got
20 less than a mile in there.

21 DR. ROSS: The issue of bridges, I
22 guess I was looking for some sort of a feeling for
23 the visual impact of the most visible bridges. I
24 guess the Stoney Creek one is -- I think that is
25 the longer one with the ---
26

27 MR. FOX: The 700 footer, yes.

28 DR. ROSS: And perhaps also the trestle
29 as well, although I gather that the trestle may in
30 fact not be visible.

29
30

MR. FOX: You will never see the trestle from the highway.

DR. ROSS: That is fair enough. Did you deal with the aesthetic quality of the bridges at all? Were any changes made there, any discussion of that?

MR. MacGREGOR: Well, the actual design of the trestle has not been determined at this point, but as we said in a document, for the most, that is a 25 to 30 foot structure contained by 75 to 80 foot trees, so under those conditions. As well, the use of bridge structures, especially at Stoney Creek, have been used to really improve the visual quality as compared to using fills, and at that point we feel the bridge structure is a very positive visual addition.

DR. ROSS: That leads directly to my next question in which I have a quote from your report, essentially referring to the trestle structure which indicates:

"What would have been by far the largest scar along the whole surface route has been turned through that structure to a little more than a subtle band across the forest."

The obvious question persists why not use that technique more frequently?

MR. MacGREGOR: Cost.

MR. TENCH: Could we have some idea of

F-4

1 the relevant costs, Mr. Fox, between running the
2 trestle and, say, an average cut and fill section?

3 MR. FOX: The cut and fill section,
4 they average about half the cost of a bridge structure,
5 and you are looking at something in the order of
6 \$8,000 a foot for a structure.

7 THE CHAIRMAN: Just a question on cost.
8 What is the total cost estimated to be on this
9 reclamation exercise? Has anybody sat down to figure
10 that out yet?

11 MR. FOX: Yes, I have it. Privileged
12 information.

13 No, I will tell you what I have allowed
14 in the estimate. I put in \$2 million to look after
15 the revegetation.

16 THE CHAIRMAN: Thank you. You had
17 a question you wanted to ask, Mr. Fox.

18 MR. FOX: Well, it was more of a
19 comment to help complete Mr. Walker's education on
20 railways.

21 You were mentioning on page 10, I believe,
22 under reclamation monitoring you had some concerns
23 about C.P. Rail inspectors be on site only part time.
24 Allow me to correct you. C.P. Rail inspectors are
25 on site at all times when construction is being
26 carried out.

27 Now, I think what you perhaps were
28 referring to were the reclamation inspectors, I would
29 think. When you are talking C.P. Rail inspectors
30

F-5 1 for construction, they are on site at all times.

2 I do not think I have anything else.

3 I asked a question about fire and I talked about
4 the others.

5 Anyway, I would like to say this, Mr.
6 Walker. I am impressed with your document, and
7 as far as I am concerned, I would like to thank you
8 for all your comments. I found them very helpful,
9 even though I still do not think you are right up
10 there scratch with engineering.

11 THE CHAIRMAN: The intent was not to
12 close the discussion off necessarily.

13 MR. TENCH: Especially with a scathing
14 remark.

15 THE CHAIRMAN: We are not going to let
16 you get the last comment. Bill Ross has got another
17 question. George Tench, you have been neglected.

18 MR. TENCH: I have been looking at that
19 old right-of-way now for 12 months and looking at
20 it from the highway it ---

21 MR. FOX: Which old right-of-way are
22 you talking about?

23 MR. TENCH: The original railway.

24 MR. FOX: Okay.

25 MR. TENCH: It obviously created less
26 havoc to the landscape than the present one seems
27 to be doing. It seems in many cases to be on the
28 same profile of mountain as the present one and I have
29 a suspicion that the techniques they used to move
30

F-6

1 dirt with in the old days caused them to be a
2 devil of a sight more careful with their engineering
3 than we seem to be at the present time when we can
4 go in there and really push it about.

5 MR. FOX: My turn?

6 MR. TENCH: Yes.

7 MR. FOX: Okay, that railway was built
8 in, well, the early part of the 1880s, and while I
9 do not have the specs of what they built it to,
10 I would suggest that when it was built it was built
11 through an extremely narrow sub-grade top, because
12 in those days the type of power that is used or
13 locomotive power in cars were very small and very
14 light.

15 Today we are operating cars that weigh
16 131.5 tons on four axles. We have locomotives of
17 a 300,000 horsepower range that have weights
18 approaching 400,000 pounds on the trains that are
19 going through that particular country today; we are
20 operating in excess of 100 cars behind locomotives.
21 Those are the big bulk trains we have, the mid-train
22 power, and if we operated those trains today on
23 that type of railroad, I would suggest, Mr. Tench,
24 you might make one trip but you sure as hell would
25 not make the second one.

26 MR. TENCH: I am not quite sure I get
27 the picture. Are you hauling that stuff over that
28 old bed now?

29 MR. FOX: That old bed in the last 100
30

F-7 1 years has been improved so much that you would
2 never recognize it from the original construction.

3 MR. TENCH: That is an interesting
4 statement because you have been in there quietly
5 cutting and chopping at that old bed, and the slopes
6 up and down from it and it still is a pretty sweet
7 sight compared to two things, I must admit, the
8 new highway and the new railroad.

9 MR. FOX: Another thing, too, if you
10 are just talking the existing railway line, not
11 the one that has been abandoned, now, my reference
12 was made to the abandoned one, okay.

13 The existing railway is for the most
14 part on a bench. If you go up there and take a
15 good close look at it, it is located on a small bench
16 and that eliminated the necessity to hoist very steep
17 side slopes that we are now into. They do have
18 a few down around Mountain Creek, but for the most
19 part that is on a bit of a bench where the slopes
20 come up and sort of flatten out a little bit and
21 go up again. You know, they were not dumb in those
22 days. They picked the easiest route.

23 DR. ROSS: You mean God did your cutting
24 and filling for you.

25 MR. FOX: Now, you know, to give you
26 a little further background on it so you can
27 perhaps assess it, every railroad in this country
28 was built initially to the standards of the power
29 and cars that existed at the time they were built,
30

F-8

1 and for the most part, they were built very cheaply,
2 the cheapest method they could possibly find. No
3 shallow fills and they would go around corners and
4 this sort of stuff, and those lines today, over the
5 length of time they have been in operation, they
6 have been improved immensely. A lot of line
7 relocations have taken place to take out the bad
8 hooks that the original builders circumvented.

9 So any relationship to what we have
10 today to what was originally there 100 years ago,
11 I can assure you is purely coincidental.

12 MR. TENCH: The only thing that gets
13 you off the hook is that blasted bench that was
14 supplied by nature.

15 MR. FOX: That is right. Well, it
16 happens to be there.

17 THE CHAIRMAN: Bill Ross, you have a
18 further question.

19 DR. ROSS: One of the objectives for
20 the visual assessment is, and I quote, "to maintain
21 the present level of scenic quality by applying the
22 appropriate mitigative measures".

23 Indeed, if that is the objective that
24 you people intend to meet, and I think we would all
25 agree and we would all be happy, what I think is
26 clear by now is that most of us have some
27 difficulty in believing that that is feasible within
28 several decades.

29 I think it is probably reasonable to
30

F-9

1 accept some deterioration and that certainly is
2 a reasonable objective. What seems to give me some
3 trouble is if I move to a different page and I
4 indicate again from the Visual Impact Assessment
5 Report, a description of the Mountain Creek bridge
6 cuts which will be, and I quote, "supporting a
7 healthy vegetative cover by 1983", then I start to
8 have a mismatch. If I refer to Mr. Polster's quote
9 which is, "successfully revegetated area", as I
10 drove by, I must admit, I was unimpressed and I
11 certainly would never have claimed that the
12 revegetation on the Mountain Creek cuts maintain
13 the present level of scenic quality.

14 So I think what clearly is the problem
15 here is in part you may be setting standards for
16 yourself which I do not think you reasonably intend
17 to meet, maintaining the present level of scenic
18 quality, at least in the short run, and therefore,
19 setting expectations which are too high.

20 Do you think that you can maintain that
21 level of quality? Do you really perceive that
22 the Mountain Creek cuts are supporting a healthy
23 vegetation cover now? I am in trouble. Would you
24 respond to that?

25 MR. FOX: Which cuts are you referring
26 to?

27 MR. TENCH: The existing one.

28 MR. FOX: What existing one, the gravel
29 pit or up on the railway?

DR. ROSS: I assumed that this was the bridge cuts.

MR. FOX: Mr. Polster was talking about the cuts on either side of the existing Mountain Creek bridge.

DR. ROSS: That is correct. I believe that is what I am talking about too.

MR. FOX: Well, be sure in your own mind because there is a gravel pit down below.

DR. ROSS: I am not talking about the gravel pit. I am talking about the bridge.

MR. POLSTER: As I pointed out in my presentation, obviously the existing Mountain Creek cuts are considerably more severe than even the most severe conditions that we expect on the new grade. Granted, we go through the same materials, but I will tell you that there was nothing done on those cuts to ameliorate the soil conditions or provide anything like suitable growth medium or anything like that. Also, they are very steep.

So, considering all that, I feel that our operational trials conducted last year were successful in establishing a vegetation cover considering the conditions of the slope.

Now, how long that cover will persist and whether we will have to maintain it with added fertilizer because of the lack of fine textured materials on that slope remain to be seen.

THE CHAIRMAN: Just so we have a

F-11

1 standard on this thing, are you saying that what
2 you have there, that you and Bill have been talking about
3 does not meet the sort of standards that have been
4 laid out in this particular ---

5 MR. POLSTER: No, I do not think it
6 does. What we have there is fairly reasonable
7 considering the conditions, but I would not agree
8 to testing it by the standards from Mr. Walker
9 because I do not think it would live up to the
10 standards.

11 THE CHAIRMAN: Does Lake Louise meet
12 these standards?

13 MR. POLSTER: No, but neither does
14 the native vegetation around Lake Louise compare
15 to the standards.

16 THE CHAIRMAN: I am not trying to be
17 tricky in my questions. I am just trying to get an
18 idea of how these standards might apply in something
19 that I can relate to. To me right now they are
20 just numbers.

21 But that is fine, I got the answer to
22 my question. I think fairly soon we are going to
23 have to break for lunch in order to give the Court
24 Reporters a bit of a rest.

25 Perhaps what we could do is finish off
26 this revegetation reclamation issue and then come
27 back say at one o'clock in order to do the tunnel
28 ventilation at that time, and after that we will
29 have our closing statements which will be pretty close
30

F-12

1 to the two o'clock that we are intending to have
2 there. Bill Ross, do you have any further
3 questions; George Tench? Any members of the audience
4 who have any questions? C.P. has been providing
5 some responses. Parks, do you have anything you
6 want to say at this time?

7 DR. LEESON: We have got some things
8 to say but it could be done in the final, if you
9 want, but I could do it in about four minutes.

10 THE CHAIRMAN: Perhaps now might be
11 the time to do it.

12 DR. LEESON: These are some short
13 comments about the morning's proceedings. With
14 regard to the visual analysis, we think that it
15 was complicated and quite thorough, and while we
16 may take some exception with the methodology and
17 some of the assumed criteria, we do not disagree in
18 the final analysis that Mr. MacGregor's work has
19 changed the design and C.P. has responded to it
20 in ways that will assist in reducing visual impact.

21
22 However, our bottom line is that we
23 are less perspective than Mr. MacGregor regarding the
24 appearance of the new line, the final appearance,
25 that is. As I have said before, we think it is
26 going to look bad, but we also do not know anything
27 more that can be done to overcome the problem other
28 than reclamation, and for that reason we are saying
29 that reclamation is very important.

30 For the vent structure, we think that

F-13

1 C.P. Rail has selected the best location and that
2 they are planning to build a structure there that will
3 be sympathetic to our visual concerns.

4 At this point we are concerned about
5 the deteriorated condition of the access road and
6 we would like to have that fixed up as soon as
7 possible.

8 Now, with regards to reclamation, I am
9 a little dismayed. After the proceedings of this
10 morning, I do not know what we are going to do to
11 look after ourselves. When two experts cannot agree
12 on the whole thing what is going to happen to us.
13 So, obviously we are going to need a lot of help and
14 as time goes on when specific plans are proposed to
15 be able to get them evaluated in a way that finally
16 we know and C.P. Rail knows what we are going to
17 get, so that we all agree what we are starting into.

18 We are simply going to need help, and
19 again, I would like the Panel's consideration of that
20 and what should be done.

21 Another point I would like to bring
22 up regarding reclamation is that it is important to
23 us that the scale of the reclamation undertaking is
24 consistent with the scale and magnitude of the
25 damage that created it. We would not like to see
26 a situation where the countryside is torn apart with
27 D-9s and then the reclamation people show up with
28 garden tractors to try and fix it.

29 The rehabilitation standards discussion
30

F-14

1 is very good and we would urge that specifications
2 and terms of reference and monitoring criteria be
3 established so that once the work is all finished
4 that we and C.P. Rail know what it was we were
5 supposed to get and we would be able to determine
6 thoughtfully and intelligently what we got and
7 respond to it if it is less than expected.

8 THE CHAIRMAN: Any further questions at
9 this time? Mr. Walker, do you want to add anything;
10 C.P.?

11 MR. FOX: No, not for me, Mr. Chairman.

12 THE CHAIRMAN: Okay, it is twelve
13 o'clock now. If we could be back by one to discuss
14 the noise acoustical evaluation and then we will
15 proceed right on to closing statements. I think it
16 is obvious we will not be meeting on Monday. I
17 think we will have this meeting over this afternoon.
18 Thank you very much.

30

1 ---UPON RECOMMENCING AT 1:00 P.M.

2 THE CHAIRMAN: If we take our
3 seats again, I think we are going to begin with
4 a presentation from C. P. Rail's acoustical
5 expert and then we have our own expert to make a
6 presentation.

7 MR. SAM LEVY (Parsons, Brinckerhoff)
8 Mr. Chairman, Members of the Panel,
9 Ladies and Gentlemen: My name is Sam Levy and
10 I am with Parsons Brinckerhoff working on the tunnel
11 ventilation system.

12 I will first provide a brief summary
13 of the tunnel ventilation system acoustical design
14 study that we have conducted and then move on and just
15 present some pertinent aspects with the aids of
16 some transparencies, which are diversions from
17 and in contrast with the high quality slides you have
18 been accustomed to seeing here.

19 The tunnel ventilation system
20 operation noise is one of the environmental concerns
21 highlighted by the assessment panel's Preliminary
22 Report of April, 1982. The primary goals of
23 ventilation system noise evaluation and design are

24 1) To minimize the potential
25 impact on the natural serenity of the surrounding
26 area;

27 2) To achieve compatibility with
28 recreational use of the land by limiting noise impact
29 areas to small localized zones,
30

PM-G-2

(Levy)

And lastly,

To avert any identifiable potential impact on wildlife.

The project group took a detailed acoustical evaluation and submitted a report entitled "Rogers Pass Tunnel Ventilation System Acoustical Evaluation Design", Final Report, and was submitted in February, 1983. The Report has since been reviewed by Panel's acoustical consultant as to the acceptability of the design criteria and engineering feasibility of achieving the above goals.

The logical sequence of steps undertaken by the project to meet the stated goals are:

1) To first establish an engineering design noise criterion consisting with known and established standards and criteria related to public health and welfare, land-use compatibility, annoyings in community, reaction of noise sensitive areas, environmental degradation, and effects on wildlife;

2) To estimate the resulting noise levels around the mid-tunnel ventilation building and the east portal fan building under the worse case vent system operation, based upon system engineering data;

3) To establish the need and degree of noise abatement measures to meet the design noise criteria, and lastly:

1 (Levy)

2 4) To develop the necessary
3 engineering specifications and testing procedures
4 to ensure the achievement of the stated goals.

5 The result of this test effort
6 are: 1) we establish a noise criterion
7 of 65 DBA maximum at 200 feet away from the vent
8 structure. This is established both as environmentally
9 sound and an engineering feasible design goal, the
10 achievement of which will result in the noise
11 environment compatible with the recreational and
12 nature preserved land-use of adjacent areas, except
13 for localized zones of at most 800-foot radius with
14 no adverse impact on noise-sensitive areas such as
15 the Summit Monument, the hotels, the Park compound,
16 the campground and nearby trails, and would limit
17 any potential noise impact on wildlife to these
18 localized zones immediately adjacent to the ventilation
19 structure.

20 This statement is affirmed by the
21 Panel's Expert Review dated April 27, 1983.

22 2) The vent system operation
23 noise levels in adjacent areas were estimated and
24 superimposed on bagman noise levels for impact
25 assessment to affirm the findings which were used
26 to establish the design criteria,

27 3) Comparisons with design criteria
28 were made and minimum silencing requirements to
29 achieve the designed goals were established with a
30

PM-G-4

1 (Levy)

2 margin of safety. In addition the engineering
3 alternatives and feasibilities of achieving the goals
4 were evaluated, as is affirmed by the Panel's
5 Review Report, and lastly,

6 4) Detailed engineering
7 specifications are being prepared to implement the
8 noise control designs and procedures are under
9 development to ensure the achievement of the design
10 goals.

11 Now I would just like to move on
12 to present some of the pertinent aspects to this
13 effort. Now these are not high quality transparencies,
14 and after all we cannot really visualize noise.
15 Now prior to discussing the acoustical design
16 aspects of the tunnel ventilation system, let us take
17 a look at a setting of the mid-tunnel vent
18 building and the east portal fan building with
19 respect to noise impact concerns.

20 The diamond-shape, and I will point
21 to it -- that is the one here, that shows where the
22 mid tunnel vent building location and the start up
23 here shows the east portal fan location. The major
24 noise emanations of concern are the inlet and
25 exhaust of the mid-tunnel building and the exhaust
26 of the east portal fan.

27 The east portal fan exhaust is
28 oriented to the east - that is north, and the exhaust
29 on the east portal is heading to the east.

30

(Levy)

1 The mid-tunnel vent building exhaust is oriented to
2 the north-east to the east up the slope and away
3 from the Trans Canada highway, and its inlet is
4 oriented to the south-west to the west, the opposite
5 direction, down the slope and towards the highway.
6

7 As can be seen the area around
8 the east portal fan is generally inaccessible to
9 the public, and as far as noise sensitive receptors
10 are concerned, the nearest hiking trails are about
11 one and one-half miles to the east and the north.
12 It is probably more than that.

13 The Summit Monument is about
14 2,800 feet north, north-west of the vent building --
15 I see other people have done surveys with the
16 distances that are more accurate than mine and they
17 are actually over 3,000 feet, and the other side
18 of the Trans Canada highway, and the Park administration
19 compound, the campground and the hotel accommodations
20 at about 6,000 feet north, north-west. Again, the
21 numbers I am using are low. The actual numbers are
22 7,000 feet. There is a nature trail about 3,000 feet
23 to the west, which is this one. This trail is now
24 maintained by Parks Canada, as pointed out by the
25 Panel's review expert. All of these are on the
26 west side of the Trans Canada highway, which is the
27 main traffic corridor serving the Park.

28 Now the fact that the mid-tunnel
29 vent building is located in the area by Park visitors
30 and concentrated with points of interest, this

PM-G-6

1 (Levy)

2 particular location deserves a closer examination
3 in terms of potential noise impact.

4 Now I have a sketch which is
5 another diversion downward from my transparencies,
6 which shows very briefly -- this is just to show
7 in general what the ambient noise environment is
8 like. This is a one-inch to 200 scale. It is a
9 working drawing, and as you can see there are
10 numbers all over the place. This is the Trans
11 Canada highway and that is the vent building and that
12 is the monument. The hotels are out of the picture,
13 much further up. What I really wanted to point
14 out there were measurements taken by project
15 staff and there were estimates made by the Panel
16 expert, using some Canadian Mortgage Association
17 data, on the ambient noise level, and generally
18 when you are close to the highway, say 30 feet,
19 about 66 DB, and when you move to 600 feet away
20 from the highway, 50-53, and about 2,000 feet away,
21 about 40. Now there are times the ambient will be
22 lower than that during the height of the traffic
23 activities. It is just to show a general picture.

24 We also have used a U. S. Federal
25 FHWA, the Highway Administration Noise Prediction
26 Model for Traffic drawn up to counters, and just to
27 show that it is generally required well with the
28 data, and that will give us a better picture of the
29 ambient situation that is there, because there were
30

PM-G-7

1 (Levy)
2 few points of measurement. We cannot really say
3 very much. So these are just lines which show
4 the 50 DB count to 55, and these are quite typical
5 of the low level traffic highway.

6 Now around the east portal, although
7 no measurements were taken, one can expect the
8 noise level to be in the lower or mid-thirties,
9 as typical of wilderness area than with the flow of
10 Beaver River.

11 Now what do these noise levels
12 mean? Perhaps the best way is to relate to some
13 quantities of phenomena that we daily encounter.
14 Now this picture just presented some normal activities
15 that we daily encounter and what their levels are
16 in terms of DBA, which is a measure of closely
17 co-response subjective human perception of loudness,
18 and used most frequently for environmental noise
19 impact assessment.

20 You can see that a truck going
21 by at 50-feet, that is a heavy truck, is about 90 DBA.
22 There is a washing machine at home at three feet
23 running is about 65. In this room, when there
24 is nobody here, it is 49-50. The LRV outside on
25 the street when it passes by is in the high
26 seventies.

27 Now I wanted to show in terms of
28 the ventilation system noise how does that compare
29 to the sound levels. Okay, we estimated that the
30

1 (Levy)

2 ventilation system without any control at 200 feet
3 away from the building was about 84 DB. The criteria
4 that we establish, that we aim to achieve with a
5 margin of safety, is 65 DBA. That is only a
6 criteria, and there is a margin of safety in there,
7 and we aim to do better than that, and being of
8 an engineering background, we go from the lower end
9 up. We want to be conservative and then we will
10 try to do better than that.

11 Now this 20 DB reduction may not
12 seem a lot; in reality, it is a reduction of 100
13 times, meaning to limit the escape of acoustic
14 energy emission to one-hundredth of its original
15 emission while providing enough air to ventilate
16 the tunnel.

17 Now the 65 DBA maximum at 200
18 feet from vent building or fan building, as
19 established by the project design criterion, to
20 fully comprehend the environmental noise impact
21 which is assessed in detail in the study report,
22 by adopting this design criteria we need to under-
23 stand a little bit about how the ventilation system
24 was designed to operate. Now during the passage
25 of the heaviest train, the east portal fan is
26 expected to operate for 25 minutes, and the mid-
27 tunnel vent building fans are then expected to
28 operate 30 minutes in various combinations. In
29 addition to this on and off feature, the four fans
30

PM-G-9

1 (Levy)

2 in the vent building, working many combination
3 modes, 28 or more -- so I am told, depending on the
4 train positions and weather conditions, show
5 some of the operating conditions, a full load.

6 At any one time one of the many
7 different system operating modes is in effect,
8 however, at no time it will involve more than
9 three fans running at or frequently below maximum
10 loads shown in this table.

11 The impact assessment made and
12 design criterians so selected are for this worse
13 case situation with three fans running a full load.
14 Thus, the worse case scenario maximizes the potential
15 noise impact and provides an effective margin of
16 safety. With this understanding, we will look at
17 the result of preliminary assessment of the
18 consequences in adopting this design criteria.

19 Shown in this table is a
20 simple assessment of what one can expect to result
21 from the vent building when the vent system is
22 operating under the worse case condition around
23 the mid-tunnel vent building. The first column,
24 distances from the building surface -- that
25 direction looked at four directions, and that is
26 the ventilation noise. That is a very simple
27 assessment method. That is just taking the design
28 criteria 200 feet and doing the normal decay of
29 sound, and that is the corresponding highway
30

M-G-10

1 (Levy)

2 noise at these positions. They can be regarded
3 more or less as being ambient noise. That is
4 the effect of the imposing when the two get
5 together after the system goes into operation.
6 It is a logarithmic kind of addition, so the numbers
7 look kind of funny, and that is the difference
8 between -- during operation versus the ambient.

9 It can be seen that in looking
10 at these numbers the significant increases will
11 be more or less limited to 800 feet within the
12 surface of the building. Now what do we mean
13 by "significant". Significant normally is anything
14 greater than 5 DBA.

15 There is an instance on the east
16 side where it is significant -- could be above
17 five, but again this a very simple method without
18 accounting for any of the extra losses they might
19 have, and in the actual design, we will show that
20 it is a lot less than that. And to the east, if
21 you remember, also it is going up the slope; it is
22 away from the highway, therefore, the ambient noises
23 are also lower. That is why you get bigger increases.

24 Now using this simplified assess-
25 ment, if we just take the distances to these
26 different noise sensitive receptors, the ventilation
27 noise at the Monument, the Park administration
28 compound, campground and hotel, will be far below
29 the existing background noise, and as such, no
30

PM-G-11

1 (Levy)

2 noise or adverse effects are expected at these
3 key receptor points, and this design criteria thus
4 will result also in a day-night average noise.
5 This is the average over a 24-hour period of 55 DBA,
6 everywhere except within this 800-foot radius, and
7 the LBM, the day-night level, of 55 is generally
8 accepted as compatible with park use to protect
9 public health and welfare and also of growth
10 potential impact on wildlife.

11 Having established the design
12 criterion, which would limit the impacted area to
13 within 800 feet of the vent and the fan buildings,
14 and would satisfy all other environmental impact
15 assessment criteria outside the limited localized
16 zone of inference, a detailed evaluation is then
17 made using mechanical and architectural plans and
18 site topography. In the evaluation we accounted
19 for mountain reverberation, building orientation,
20 and et cetera, and silence of performances were also
21 evaluated.

22 I will show here what the results
23 are. This picture represents the distance from
24 the building surface and the sound level, and that
25 is on the intake side of the building, the exhaust
26 side of the building and to the sides of the
27 building. You can see at 200 feet we will be, in
28 fact, much more below our 65 DBA criterion, at
29 least, we have confidence that this can be achieved.
30

1 (Levy)

2 Now as a comparison, this would
3 show -- here is the design after control and that
4 is the un-silence system, there is a substantial
5 drop. Shown also here is a typical open vent
6 system that is most often used in highway and rail
7 tunnel vent systems, and as you can see most of
8 them are very, very high -- much, much higher.
9 The size of these fans and how they sound can only
10 comprehend if you go facing one of these fans. If
11 you stand 100 feet or 200 feet, it can probably
12 blow you away, if you are my weight.

13 Now to achieve the design
14 objective we are currently developing acoustical
15 specifications of fans and silencers, which an
16 equipment supplier will have to comply with, and
17 furthermore, some field test procedures of acoustical
18 performance are being developed for quality
19 assurance purposes, and by the way, there are no
20 on-the-book procedures for doing that, but we are
21 making a special effort to develop these procedures
22 for implementation.

23 There are other back-up design
24 features that we have considered and we are keeping
25 them in our pockets. We are considering perhaps
26 additional dot lining or wad insulation if that
27 is really necessary. At this point we are pretty
28 confident that with the design features that we
29 are building in, we can achieve this without going
30

1 (Levy)

2 to these back-up procedures.. That is all.

3 Oh yes, I only wanted to mention that all these
4 things that I have used, they are in the report,
5 so anybody who is interested, they can go through
6 the report.

7 THE CHAIRMAN: Thank you for the
8 presentation. I think I would like to have our
9 own Panel technical expert come up now and make his
10 presentation and then we will have an opportunity
11 for any questions from the various people.

12 If you could come up and sit up here, Mr. Kennedy.

1 (Kennedy)

2 MR. DOUG KENNEDY (Harford, Kennedy &
3 Wakefield Limited): I am Doug Kennedy of Harford,
4 Kennedy Limited, Consultants.

5 Members of the Panel, ladies and
6 gentlemen, most of the background I think has been
7 presented already so I will keep this fairly brief.

8 At last year's public meetings a number
9 of potential noise sources were discussed including
10 construction noise and tunnel ventilation system
11 noise. It was concluded that while construction noise
12 might be annoying to some park users, it will be
13 temporary in nature and therefore tolerable.
14 Noise from the ventilation system, however, warranted
15 further investigation.

16 Over the past year, C.P. Rail has
17 carried out a thorough study on this subject.

18 Two acoustical objectives have been
19 noted by C.P. Rail's consultant: One, that the
20 day night sound level, LDN, should not exceed 55
21 DBA except within 800 feet of ventilation buildings;
22 and two, that no environmental degradation, that is
23 increases in existing noise level, should occur
24 except within 800 feet of the buildings.

25 It is my opinion that the first objective
26 is reasonable considering the general nature of the
27 Park, and the second objective is obviously desirable
28 if it can be achieved.

29 In order to simplify engineering design
30

H-2

1 (Kennedy)

2 calculations and to permit a straight-forward means
3 of inspection upon completion, the criterion of 65
4 DBA maximum at 200 feet has been proposed. It is
5 reported that if this criterion is met, both of the
6 acoustical objectives noted previously will be
7 satisfied.

8 Having reviewed the acoustical design
9 calculations, it appears to me that the proposed
10 silencing measures will ensure a maximum noise level
11 of 65 DBA or less at 200 feet from the ventilation
12 buildings. Having verified this, further analyses
13 were reviewed to ensure that given a level of 65
14 DBA at 200 feet, the LDN will not exceed 55 DBA
15 and furthermore, no degradation will occur beyond
16 800 feet.

17 It was my conclusion at the first
18 objective, that is of achieving an LDN less than
19 55 will be realized. However, the question of whether
20 any degradation will occur beyond 800 feet required
21 some clarification. It is suggested on page 25 of
22 the consultant's report that the criterion for
23 environmental degradation by an intruding noise is
24 audibility, and to be inaudible, the level of the
25 intruding noise needs to be at least 5 DBA below
26 the previously existing background noise level.
27 The reason for this is that the human brain can
28 detect a sound which is quieter than the background
29 level if it has some identifiable characteristic, such
30

H-2

1 (Kennedy)

2 as the tonal quality which is typical of fan noise.

3 The consultant then states on
4 subsequent pages that to be significant or readily
5 noticeable, the sound level must increase by 5
6 DBA. This latter statement would be true if the
7 fan noise had no tonal quality. However, since
8 there will likely be a tonal quality, the earlier
9 statement that the intruding noise will be audible
10 at 5 DBA below the background noise is correct and
11 should be used as a criterion for environmental
12 degradation.

13 On this basis, fan noise may be
14 audible at distances in the order of 2,000 feet
15 rather than 800 feet in some directions if the
16 maximum allowable level of 65 DBA at 200 feet
17 actually occurs. This does not necessarily present
18 a problem, however, since the whole analysis is
19 based on a worse case situation which will only
20 occur over limited periods of time.

21 Furthermore, the proposed fan
22 silencers will likely result in levels below 65 DBA
23 at 200 feet except perhaps at the east portal where
24 there does not appear to be any safety margin.

25 It should be noted that due to the
26 relatively high levels of noise along the highway,
27 noise from the ventilation system will on most
28 occasions be inaudible at the Summit Monument and
29 at the nearby hotel. It may provide some reassurance
30

H-3

1 (Kennedy)

2 to all concerned that during a recent visit to the
3 site I carried out the following brief experiment.
4 An airhorn was sounded at the site of the mid-tunnel
5 ventilation building. A resultant sound was
6 measured both at 200 feet from the horn and also
7 at the Summit Monument. The measured sound
8 attenuation between 200 feet and the Summit Monument
9 was in close agreement with the predicted value of
10 attenuation.

11 In conclusion, it is my opinion that
12 C.P. Rail and its consultant have done a comprehensive
13 job in analyzing the potential effects of noise from
14 the tunnel ventilation system.

15 I would recommend that the basic
16 acoustical criterion from this point on should be
17 to achieve 65 DBA or less if possible at 200 feet
18 from the ventilation buildings. Given C.P.'s
19 assurance that the ventilation system will be
20 constructed to achieve this, then the resultant noise
21 should be compatible with the Park environment.

22 THE CHAIRMAN: Thank you for your
23 presentation. Perhaps if we could have C.P.'s expert,
24 if you are finished?

25 MR. KENNEDY: Yes.

26 THE CHAIRMAN: C.P.'s expert up at the
27 front here and then maybe we could provide an
28 opportunity ---
29

30 The question I have relates to something

H-3

1 that came up in one of the earlier meetings and
2 that was the question of whether anything further
3 could be done. In the event that worse comes to
4 worse and this 65 DBA level was not achieved, I
5 thought I heard the suggestion at one of the other
6 meetings that there could be some lining of some of
7 the shafts or vents. Could you perhaps explain to
8 me how much extra silencing that could give you and
9 is that something you can retrofit in or do you have
10 to build it right into the building?

11 MR. VAN LEE: It can be retrofitted in
12 and the problem with the lining of the material
13 achieves some high frequency attenuation in addition.
14 However, the material -- we are looking at some
15 materials that are anti-corrosive, can be washed,
16 can stand the wind load in it. We have located one
17 such perspective material and we are looking at it.
18 We have some installation diagram on that, so
19 if worse comes to worse, we can definitely bank on
20 that.

21 However, we are trying to really tighten
22 up the engineering specifications, contract
23 specifications and we are instituting in our
24 contract specifications rigorous testing methods
25 once the fan -- the fan actually has to go in the
26 start-up testing anyways for mechanical performance.
27 So we would be doing acoustical performance at
28 the same time with both the fan and the silencer.

29 THE CHAIRMAN: Bill Ross, you have a
30

H-4

1 question.

2 DR. ROSS: I was perhaps going to
3 pursue that. Mr. Kennedy, I wonder first if you
4 could provide us with your assessment of whether
5 the silencing measures which are proposed are state-
6 of-the-art, that is, you can sort of buy them off
7 the shelf or are they at the frontiers and therefore
8 pushing everything that acoustical engineers can
9 do? How certain are we that the mitigation measures
10 currently proposed will work?

11 MR. KENNEDY: It is hard for me to
12 comment on that, having not, you know, checked into
13 the suppliers' products in detail, but it was my
14 general reaction on reading the description that
15 the silencers proposed were sort of on the upper
16 end of what is available. In other words, they
17 were high performance models, but on the other hand
18 I do not think we are really sort of breaking new
19 ground here. They are certainly not experimental
20 devices or anything.

21 DR. ROSS: Do you have any
22 comment on that?

23 MR. LEE: I would say that is pretty
24 much true. The silencers we are getting, they are
25 available. They are not really specially made.
26 However, we are looking at five different suppliers,
27 two of them have special types which have only
28 recently, in recent years, been tested, and we are
29 looking at these and we will be putting out contract
30

H-5

1 specifications and inducement to have these
2 specialized so-called resident type silencers, which
3 does a little bit better in cutting down the tunnel.

4 DR. ROSS: Have they been field tested
5 at all?

6 MR. LEE: Yes. Some of them have been
7 installed in very large industrial applications
8 and they have been tested.

9 DR. ROSS: To your specifications?

10 MR. LEE: To very similar specifications.

11 DR. ROSS: Thank you.

12 THE CHAIRMAN: George Tench, do you
13 have any questions?

14 MR. TENCH: No.

15 THE CHAIRMAN: Does anybody have any
16 further questions concerning the presentations on
17 this particular topic? If that is the case, I would
18 like to thank both of you for making the presentations
19 on this topic and move into the subject that we
20 were scheduled to discuss this afternoon which is
21 closing statements.

22 MR. FOX: One more, air quality if
23 you want to hear it. If you do not, that is great.

24 THE CHAIRMAN: I did not realize that
25 was on the schedule.

26 MR. FOX: Yes. You are going to get
27 the whole works whether you like it or not, Mr.
28 Chairman.

29 THE CHAIRMAN: You keep slipping these

H-7

1 (Jandali)

2 DR. TAREK JANDALI (Environmental
3 Services Ltd.): I can reassure the Panel I just
4 have a brief statement, two pages. However, the
5 statement itself will summarize the results of the
6 report, so I will not delve into that.

7 But in Parks' submission there were some
8 comments made with regard to air monitoring, and I
9 thought perhaps I could offer some suggestions to
10 the Panel as to how they could resolve that issue.

11 Further to submissions made to the
12 Rogers Pass Environmental Assessment Panel during
13 April 1982, changes to the location and
14 specification of the ventilation system dictated a
15 review of potential effects of air emissions.
16 Therefore, an assessment was conducted on behalf of
17 C.P. Rail, and a report titled "Assessment of Impact
18 of Air Emissions from Ventilation of Rogers Pass
19 Tunnel" was prepared and submitted to the Panel.
20 The purpose of this brief is to present a summary of
21 methodology used in the assessment and conclusions
22 reached.

23 Dispersion calculations were performed
24 to estimate maximum ground level concentrations of
25 oxides of nitrogen, as NO_2 , since they are the largest
26 single pollutant emitted from the tunnel. Two
27 distinct dispersion models were used: One, the
28 model STACKS developed by the Alberta Environment was
29 applied to predict maximum ground level concentration
30

H-8

1 (Jandali)

2 associated with wind; and two, a simple box model
3 developed by ESL was used to estimate concentrations
4 during prolonged periods of calm. These models
5 were applied separately for a six and a five unit
6 train with a 15,000 ton trailing load. Furthermore,
7 calculations were performed for summer and winter
8 conditions, as well as for south and north wind to
9 account for differences in surrounding topography.

10 For meteorological conditions associated
11 with wind, results indicate that maximum hourly
12 ground level concentrations were estimated to be
13 .18 ppm and .15 ppm NO_x for the six and five unit
14 model trains respectively. These predicted maximum
15 ground level concentrations under worse case
16 meteorological conditions and during maximum frequency
17 of trains are less than the Federal Government
18 maximum acceptable guidelines of .21 ppm of NO_2 for
19 one hour. Furthermore, and this is important, the
20 location of points of maximum impingement are
21 far removed from any human activities within Rogers
22 Pass.

23
24 Analysis of the frequency of occurrence
25 and duration of calm conditions indicated that
26 periods of up to nine hours can occur. These
27 conditions can give rise to potential pollutant
28 accumulation in the relatively narrow Rogers Pass
29 Valley. Model results indicate that maximum hourly
30 average ground level concentrations in areas

H-9

1 (Jandali)

2 associated with human activities are estimated at
3 worse case to be .18 ppm and .13 ppm during summer
4 and winter conditions respectively. These levels
5 are also well below the Federal Government guidelines
6 of .21 ppm of NO₂ for one hour.

7 These predictions are based, i.e. the
8 calm wind predictions, are based on the assumption
9 that the pollutants are uniformly mixed in the valley
10 air space. Often during calm, stable atmospheric
11 conditions will prevail and it is recognized that
12 mixing will be limited. Therefore, these conditions
13 will result in larger concentrations in a thin layer
14 of air aloft, i.e. above the exhaust exit. Ground
15 level concentrations in areas associated with human
16 activities within Rogers Pass will therefore be
17 considerably less.

18 Finally, in view of the manner with
19 which the emissions are discharged into the
20 atmosphere, plume trajectories in the vicinity of
21 the exhaust points were calculated in order to
22 evaluate the likelihood of pollutant impingement on
23 trees uphill from the ventilation building. The
24 findings indicate that the plume will pass over the
25 tree tops and that it is unlikely any serious damage
26 to foliage could result from exhaust emissions.

27 This, Mr. Chairman, concludes my
28 summary of the report, and I thought perhaps if the
29 time was appropriate I would just like to raise a
30

4-10

1 (Jandali)

2 few points concerning the monitoring issue that was
3 raised by Parks Canada.

4 In general we agree with the principle
5 of background monitoring and then monitoring post-
6 operation to determine the impact of a resulting
7 operation. However, I would like to start off with
8 some general comments and get back to the specific
9 points of C.P. Rail. We personally are involved in
10 such a program for Northeast Coal in Prince Rupert
11 where coal is not flowing and yet a program is fully
12 underway.

13 If NO_x emissions from the shaft are
14 to be ultimately monitored, their location should
15 be at points of maximum impingement because we are
16 not talking about very large concentrations. That
17 would put the location of monitoring points
18 approximately at an elevation of 4700 feet and
19 approximately a quarter mile north and south of the
20 vent building locations.

21 These points of monitoring require
22 power, require access and maintenance and the
23 locations are very close to the edge of the avalanche
24 path. Furthermore, if the reason for monitoring
25 NO_x is to implement remedial measures should the
26 problem deteriorate, the exercise is futile because
27 nothing can be done to eliminate emission of NO_x
28 from tunnel ventilation.

29 Location of a monitoring trailer at
30

H-11

1 (Jandali)

2 Parks Canada compound will record mostly vagueal
3 emissions and it will detect very little contributions
4 from the vent shaft.

5 We recognize that modelling techniques
6 are approximate at best, but we believe that the
7 confidence limit in those techniques is sufficient
8 to permit us to make a statement in the sense seeing
9 that the contribution at the Parks compound
10 will be very, very minimal indeed, and putting a
11 trailer down there or a monitoring situation down
12 there will not necessarily monitor effects of the
13 stacks.

14 Now I would like to make a couple of
15 more specific comments concerning the Rogers Pass and
16 perhaps place these emissions in perspective. In
17 our predictions we have always assumed worse case
18 scenarios and assumed very conservative assumptions.
19 In particular, all of the nitric oxides emitted
20 which are composed approximately 75 percent NO and
21 25 percent NO₂ have been converted to an equivalent
22 NO₂ in their entirety. This is conservative largely
23 because, and it had to be done for the following
24 reasons in that no guidelines exist for NO, and
25 secondly, it is conservative because the toxicity of
26 NO is about five times less than that of NO₂.

27 Finally to put the emissions further
28 in perspective for perhaps the people who are not
29 so well versed with dispersion in that the emissions
30

H-12

1 (Jandali)

2 that we are dealing with here that are coming out
3 of the tunnel, we are dealing roughly with one train
4 every hour, a total of 24 trains per day, not all
5 of them are these maximum unit trains. The vent
6 shaft basically ventilates one-half of the tunnel
7 and that is the west half of the tunnel.

8 Most of the volume of air emitted from
9 the vent shaft is basically air drawn in from the
10 west portal, so there is a terminus amount of
11 dilution that takes place before the air is emitted
12 from the shaft itself.

13 As a result, for comparison, a train
14 travelling in the west portion of the tunnel, i.e.
15 approximately four miles, give or take some
16 distance, and diluted and emitted at a high point
17 in the Valley will result, in my opinion, in less
18 concentration within the Valley than would have been
19 the case if the train was allowed to travel a surface
20 route.

21 In view of all of these points above,
22 it is very difficult for me on a technical basis to
23 justify a monitoring program.

24 Thank you.

25 THE CHAIRMAN: Thank you for your
26 presentation. Panel, do we have any questions?
27 Perhaps Parks might like to at this time if they
28 wish to make any further response. They raised the
29 question of monitoring originally. Are you now
30

H-13

1 satisfied following this presentation or do you
2 wish to reserve your position and get back to us
3 after you have consulted your expert?

4 DR. LEESON: I think that since Dr.
5 Jandali and Mr. Faulkner live in the same city, it
6 might be good for them to talk, perhaps even over
7 the telephone and for the two of them to decide what
8 is best. It does not look very prospective from
9 this end.

10 THE CHAIRMAN: Do you think you could
11 raise that, then, with the AES person, since he is
12 not party to all the discussions that have gone on
13 here, and suggest that perhaps he might like to chat
14 with the expert from C.P. Rail and you know, one
15 or other can phone.

16 DR. LEESON: Would that be acceptable to
17 C.P. Rail and to Dr. Jandali? That certainly would
18 be all right for us.

19 DR. JANDALI: Mr. Chairman, I know Don
20 Faulkner very well and he and I had touched on the
21 subject before coming to the hearings. We have not
22 resolved anything pending the outcome of the hearings.

23 THE CHAIRMAN: Perhaps if you do resolve
24 it you can let us know what you have or if there
25 is an outstanding difference, let us know, in any
26 case.

27 DR. LEESON: That will be fine with us.

28 THE CHAIRMAN: Any questions? Bill
29
30 ROSS.

H-14

1 DR. ROSS: Just briefly. The report
2 you gave tracked the plume center line and observed
3 that it was well away from the trees. What are the
4 concentrations off the center line? Do they have
5 any concern for the trees because if the trees do
6 not continue growing then the visual impact may
7 deteriorate as well if there were any impact on the
8 trees.

9 DR. JANDALI: Good question, Dr. Ross.
10 Actually we looked at the vertical and horizontal
11 co-efficient that is associated with the center line
12 plume and for a distance of that short there is
13 very little dispersion that takes place until the
14 momentum jet is initially dissipated, and by then
15 the plume is about 100 metres above the trees.

16 DR. ROSS: Thank you.

17 THE CHAIRMAN: Any questions from
18 members of the audience? That being the case, I
19 would like to thank you for your presentation and
20 I know -- I am going to get to the closing comments
21 from the various parties in a moment unless Mr.
22 Fox has any more consultants.

23 MR. FOX: I have run out.

24 THE CHAIRMAN: I know Bill Ross has
25 a question that he wants to put to Parks Canada.
26 I think what we will do before going to closing
27 statements, and I believe Parks Canada will make a
28 closing statement and C.P. Rail, that we will allow
29 a last brief opportunity for any questions to be
30

H-15

1 put forward, and I will start with Bill Ross.

2 DR. ROSS: The only one I wanted to
3 do was to reiterate or I guess open the opportunity
4 for Mr. McKnight or Mr. Gallacher to make any
5 suggestions on improving the specs or whatever for
6 the Environmental Coordinator or the Environmental
7 Committee. I mentioned to you in Golden that I was
8 going to come back and ask you that, so if you have
9 any suggestions that you would make, I would be happy
10 to hear them now or perhaps they may be part of
11 your final statement in which case we will get to
12 them at that time.

13 MR. GALLACHER: They are not part of
14 our final statement, but I would like to meet with
15 the Environmental Committee first and discuss it
16 thoroughly with them before we make any decisions
17 if you are in agreement with that?

18 DR. ROSS: Will that happen before the
19 end of the month?

20 MR. GALLACHER: Yes.

21 DR. ROSS: You can get us any response,
22 then, from the Committee before the end of the month?

23 MR. GALLACHER: By the end of the
24 month I will.

25 DR. ROSS: Thank you very much.

26 MR. MCKNIGHT: The issues that were
27 raised in Golden we have had some thoughts about.
28 I sincerely hope that C.P. does not hire too many
29 more consultants because every time they give me
30

H-16

1 about eight more jobs I have to do. So I hope
2 that is getting close to the end of it.

3 The issue of resolving disputes is
4 really no clearer in my mind than it was before.
5 It is something you gentlemen can maybe consider.
6 In the past the whole issue of whether you are trying
7 to merely correct a problem or whether there is an
8 actual punitive -- do you go beyond correcting the
9 problem merely to try to ensure that it does not
10 happen again. Those sort of areas, and in addition
11 the amount of manpower and time, the level of
12 inspection that should be anticipated for a job this
13 size. Unfortunately we did not get into detailed
14 discussions on that.

15 I think that there is potential for
16 using the C.P. inspectors to monitor a lot of the
17 environmental conditions because they are included
18 in the contracts. I have talked to other people about
19 that who feel that it is a little bit of a naive
20 thing for me to suggest in that you do not get the
21 fox to guard the chicken house. That was not very
22 good, was it.

23 MR. FOX: Just keep on.

24 MR. McKNIGHT: I do not know if those
25 things are referred to as Freudian slips or what.

26 But I feel relatively confident that
27 we can, you know, resolve this at the Environmental
28 Committee level and I think some excellent points
29 were raised about the composition of the committee
30

H-17

1 and I think there probably is room for improvement.
2 There is room for probably more technical expertise.
3 I appreciated Mr. Fox's comment in Golden about
4 other people. At times I feel that I am out there
5 by myself and that I have to be the initiator of
6 all endeavours towards environmental protection.
7 There does not seem to be in a lot of cases other
8 people out there coming up with initiatives.

9 I guess that is the end of my statement,
10 thank you.

11 THE CHAIRMAN: Any further questions
12 from anybody at this time? Mr. Fox, do you have
13 any final questions? You will have an opportunity
14 to make a final statement at the end.

15 MR. FOX: No, I have no further questions.
16 Thank you, Mr. Chairman.

17 THE CHAIRMAN: That being the case,
18 I guess I will call on Parks Canada to make their
19 statement and then go to Mr. Fox and then I will
20 make some short concluding remarks of my own. So
21 if you would like to either use the microphone or
22 come up and make any concluding statements you wish to
23
24
25
26
27
28

H-18

1 (Leeson)

2 DR. BRUCE LEESON: Mr. Chairman, I
3 feel that Canadian Pacific Rail has responded to the
4 earlier directions of the Panel with respect to
5 conducting further research, and I also feel and
6 can advise you that C.P. Rail has responded to Parks
7 Canada's request in the interim in many of our
8 meetings for the conduct of further research and
9 provision of additional information.

10 We conclude that C.P. Rail's
11 consultants have done good work and although the
12 proceedings over the last couple of days have
13 revealed that there are a number of loose ends which
14 must be attended to, we think that they can be
15 within the context of the Panel's deliberations as
16 you carry out your responsibilities, and also in
17 further technical workshops between Parks Canada
18 and C.P. Rail and possibly with input and assistance
19 of the Panel's technical experts. We would be
20 able to focus on unresolved issues where we would
21 be forced to achieve a compromise and to establish
22 agreed goals.

23 So with that prelude, I again would
24 reiterate what I said Wednesday night, that we think
25 the Panel can approve the project but that approval,
26 however, should be conditional upon Mr. Fox's very
27 exquisite verbal and red book written commitment
28 that they will employ a state-of-the-art technology
29 in protecting the environment of Glacier Park and
30

H-19

1 (Leeson)

2 reclaiming those Parks that are subject to
3 unavoidable impact.

4 I would like to leave you with four
5 points for your consideration. Our number one
6 priority in the whole project is that reclamation is
7 the major concern. The second point of priority is
8 that we do not want the work camps or the parking
9 areas in the Park. The third point is that we
10 would like to participate in consideration of further
11 options which could be utilized to minimize terrain
12 impact where that would be significantly helpful in
13 reclamation objectives. For example, could retaining
14 walls be used for the purpose of flattening the slope
15 if it is considered that the slope is in a steep
16 and difficult place that would compromise reclamation.
17 The fourth one is directly for the Panel's
18 consideration, and that is that we request assistance
19 in some way, either directly from you or recommendation
20 from you for our Minister in order to be able to
21 conduct technical reviews of the specific designs and
22 plans that are put forward by C.P. Rail and their
23 consultants in the months to come in order that we
24 can do an intelligent and thoughtful job of analyzing
25 what is being proposed and to be able to ensure the
26 concerned public that our agency is managing this
27 project in Glacier National Park as responsibly as
28 possible. Thank you.

29 THE CHAIRMAN: Thank you very much
30

H-20

1 (Fox)

2 for your comments, Dr. Leeson. Thank you very
3 much for your participation and the participation
4 of your colleagues, Mr. Gallacher and Mr. McKnight
5 during these hearings. It has been very useful to us.

6 I would now like to pass to Mr. Fox
7 for his concluding remarks.

8 MR. JOHN FOX: Thank you, Mr. Chairman.
9 I only have about three points but I would like to
10 discuss them. There has been during this session
11 a lot of discussion concerning the width of right-of-
12 way which the railway is requesting. Parks Canada
13 has expressed their concern in this regard.
14 Railway rights-of-ways vary in width in Canada from
15 66 feet in width, generally found in parks in some
16 of our eastern provinces to 200 feet in width across
17 most of our prairie provinces.

18 In areas where steep side slopes exist,
19 the width of rights-of-ways is always such that
20 the full extent of cuts and fills are within the
21 right-of-way boundaries. The total width does vary
22 to suit the conditions which exist. The actual area
23 required on the Rogers Pass project surface route
24 for clearing and construction amounts to 158 acres.
25 The remaining acreage is required to straighten out
26 the property lines to provide a basis for a proper
27 legal land description. It would be next to
28 impossible to provide a legal description of land
29 if only the slope stake limits were followed.
30

I-1

1 (Fox)

2 In this case, the required width is
3 dictated by the size of the cuts and fills
4 necessary to construct the new railway line. The
5 existing railway line, which is the one Mr. Tench
6 and I discussed here some time ago, which is located
7 in a more favourable location, being on a bench,
8 has a similar varying width of right-of-way which
9 can be seen on the exhibits presented to this hearing.

10 As has been explained a number of times,
11 the main thrust of Parks Canada and the intervenors
12 and even your own witnesses have indicated that
13 the visual impact is one of the most important
14 considerations to be taken into account in the
15 design of this railway line.

16 In all aspects of our design, the
17 visual impact has been our major consideration.
18 Indeed, my own staff at times consider me to be
19 paranoid in insisting that in all of our design
20 considerations this must be of paramount importance.
21 The alignment design, which has been presented, has
22 met all of Parks Canada's concerns and suggestions
23 to minimize the visual impact. During our one week
24 workshop with Parks Canada they, at that time, were
25 most pleased with how we had handled this problem.
26 If one is to screen the proposed railway to the
27 maximum extent, you have to, in terrain such as we
28 are building upon, keep the upper slope cuts to a
29 minimum and make use of the tree screen on the
30

I-2

1 (Fox)

2 lower slope. Unfortunately, the steepness of the
3 side slopes in the area between Rogers and the
4 east portal of the short tunnel are such that
5 long downhill side slopes are unavoidable.

6 We have used retaining walls very
7 extensively in our design, the cost of which
8 estimate-wise now exceeds some \$15 million alone.

9 The use of retaining walls in the
10 downhill slopes will not improve in any manner the
11 visual impact as the large majority of the downslope
12 fills are not seen due to adjacent tall trees.
13 The total acres required of some 31.7 over some ten
14 miles of route in terrain such as exists in the
15 area under discussion is not at all out of proportion.

16 The alignment presented has been
17 carefully thought out and engineered to the highest
18 standards possible.

19 I cannot think of any reason why
20 additional money has to be spent on large and very
21 expensive retaining walls such as would be required
22 to save some 10 to 15 acres of land. The relative
23 cost of this land based on the cost of retaining
24 walls would amount to something like \$1.4 million
25 per acre.

26 In addition to being responsible for
27 all environmental consideration, one also must
28 keep in mind what this line of railway is required
29 for, and that is carriage of this nation's goods
30

I-3

1 (Fox)

2 to the marketplace. This, then, places a
3 responsibility on C.P. Rail and I might also add
4 the Panel, to ensure the total cost of the work is
5 reasonable and that in the final equation Canadians
6 do not have to pay more than they should for
7 transportation services.

8 Camps for the construction workers.
9 Again, much has been said concerning work camps in
10 Glacier National Park. C.P. Rail has made a
11 concerted effort to develop a camp standard which
12 will minimize damage to the Park. We have employed
13 top notch people to design the camps, the layout,
14 the structures and facilities so they will be
15 attractive, neat and will not detract from the
16 areas we propose to locate them in. Indeed, some
17 of the existing permanent structures in the Park
18 are not as attractive.

19 Proposed sites, that is, Beaver Pit
20 Camp and Glacier Camp will be in locations of former
21 camps. Very little clearing is required. Both
22 sites cannot be seen from the highway or viewpoints.
23 C.P. Rail has indicated that all environmental
24 requirements will be met.

25 The question of bear protection fences
26 has been thoroughly looked into. It is indeed very
27 difficult to understand why temporary camps such
28 as proposed require fencing when all other inhabited
29 areas within the Park in the same animal environment
30

I-4

1 (Fox)

2 do not require such fences. An experienced camp
3 operator who has operated such camps throughout
4 B.C. and northern Alberta has spoken in this regard.

5 The people who would object or consider
6 the need for such fences have had little or no
7 experience in the operation of any such establishment.
8 Indeed, Parks Canada people themselves have
9 indicated little or no problems with bears around
10 the establishments in the Park, including Glacier
11 Park Lodge Hotel.

12 To locate these camps outside the
13 Park boundaries will add \$33 to \$38 million to the
14 cost of the project for no acceptable reason and
15 delay the completion of the project beyond 1988, which
16 is the year projected to be the time when C.P. Rail
17 will reach its capacity limit on moving trains over
18 this territory. Parks Canada has stated that
19 their policy is to allow no such establishments within
20 the Park. I can see this policy in relationship to
21 permanent establishments but suggest that such a
22 policy does not exist for those of a temporary nature.
23 If such a policy exists, then how could we have
24 had both the Beaver site and the Flat Creek site
25 approved last year prior to the 1982 Panel hearings.

26 Mr. Chairman and members of the Panel,
27 the location of these work camps is of paramount
28 importance to the successful completion of this
29 important project. The area concerned is in one
30

I-5

1 (Fox)

2 of the heaviest snow areas in Canada and we must
3 have camp locations as close to the work site as
4 is possible so that during the winter months delays
5 due to snow and avalanche problems have minimum
6 impact on loss of work time.

7 In addition, I might state this. We
8 have indicated that C.P. Rail will be operating these
9 camps. If that is the case, and it will be the case,
10 then our police force comes into the picture and
11 we can then use our own forces to police these
12 camps.

13 Visual impact and terrain impact are
14 words that must be looked at very carefully and
15 used in their proper context. I am sure you and your
16 Panel members will be careful in this regard.

17 C.P. Rail has committed itself to
18 minimize both the visual and terrain impact. All
19 other environmental requirements will, and you have
20 my assurance, be carefully controlled, monitored and
21 be looked after to the highest standards.

22 As mentioned in Golden, it is my
23 intention to have on site during the actual
24 construction an experienced, professional
25 environmentalist to ensure that these important
26 aspects of the construction project are fully and
27 adequately protected.

28 Mr. Chairman, I would like to thank
29 you, your Panel members and your experts for the
30

I-6

1 (Fox)

2 effort you have all carried out. I would, however,
3 like to express to you the importance of releasing
4 your final report on this project as quickly as
5 possible. We in C.P. Rail still have a lot of work
6 to do and your input will be of paramount importance
7 to ensure the successful completion of all aspects of
8 this project.

9 I would also like to thank my own staff
10 and all of C.P. Rail's consultants for the excellent
11 effort they have all put forth to enable you and
12 your Panel members to better appreciate what we are
13 to build and how it will be done. Thank you very much.

14 THE CHAIRMAN: Thank you for your
15 concluding remarks, Mr. Fox.

16 I earlier thanked Parks Canada for their
17 input during this process. I would now like to take
18 this opportunity to thank C.P. for the considerable
19 amount of information that they have brought forward,
20 and aside from some of my joking comments about the
21 number of consultants that you had, that was
22 extremely valuable information and I would like to
23 compliment the consultants on their input during
24 this process. I would also like to thank our own
25 technical experts for coming along.

26 I would finally like to thank the Court
27 Reporters who have been faithfully reporting all
28 of this information which we are now going to have
29 the job of going away and trying to digest and as
30

I-7

1 speedily as possible and putting together in the
2 form of a report to the Minister of the Environment.

3 The Minister of the Environment, of
4 course, is responsible for release of the report if
5 he wishes, and all previous reports have been made
6 public and made available to all interested parties.

7 The Panel's mandate and task will be
8 to recommend the best way for this project to proceed
9 with minimal impact on the environment. That was
10 the job that we were given to do and this is our
11 final report that we were asked to write by the
12 Minister.

13 I think with that point I would just
14 close off the sessions here and hope to see you all
15 again some time. Thank you very much for coming along.
16 ---Whereupon the hearing adjourned at 2:15 p.m.
